represented at the Wenner-Gren conference, the prospect of new hominid began to stir interest. During Johanson's second expedition to Hadar, he found Lucy at Locality 162. Lucy was described as a three-and-a-half-foot-tall, bipedal hominid with a small brain. Unlike larger jaws found at the site, Lucy's jaw was V-shaped with one cusp premolar. This fact led Johanson to believe that Lucy was an early representative of australopithecines. This find would only be outdone by the discoveries that followed during the next season.

The third season would prove to be most successful. On a slope known as Site 333, Johanson and his team found bones of what appeared to be a band of hominids who met their demise, only to be uncovered by the eroding rains of Hadar. Although the site lacked animal remains, it yields enough evidence to suggest that these hominids were not related to Lucy, the hominid discovered the previous season. These hominids were considered primitive *Homo* and dubbed "the First Family." The fourth season at Hadar was used to recover the remaining fossils for interpretation. Besides the recovery of other fragments including an exquisite jaw, the recovery of stone tools was an additional triumph. Although tools of Oldowan and Acheulean were well known and dated, the tools at Hadar would prove to be nearly impossible to date, leaving much to interpretation in the following months.

Interpretation of Johanson's evidence created taxonomical issues for the various hominids discovered up to Johanson's find. Opinions on the placement of this hominid spans the spectrum, creating havoc with the established descent of our own species. The traditional family tree before Johanson's discovery was *A. africanus* leading to *H. habilis*, then *H. erectus*, ending with our own species *H. sapiens*. The *A. robustus* was seen as an extinct branch splitting around 1.5 million years ago; however, Johanson's discovery of *A. afarensis* changed that view. With the dating of *A. afarensis* going back 3.5 million years, the Johanson specimen would

be considered the oldest hominid to date. According to Johanson and White, *A. afarensis* is ancestral to all known hominids. Leading to our species, *A. afarensis* led to the *H. habilis*, *H. erectus*, and *H. sapiens* (all Homo species having association with tools). On the *Australopithecus* side, the extinct line leads from *A. afarensis* to *A. africanus*, to *A. robustus*. When considering the age, bipedality, and location, the logical placement of *A. afarensis* seems to support Johanson's conclusion. Although there have been more discoveries and phylogenetic analysis in recent years, Johanson's discovery remains an important part of human evolution.

DONALD C. JOHANSON

Donald Carl Johanson, an American anthropologist, is also known as Benjamin Earl Johnson, and as Ayubu Johnson. His legacy includes important fossil discoveries that have expanded the scant knowledge previously available on human origins, adding new species to science and new proposals for arranging the human family tree.

In 1972, Johanson and Maurice Taieb, a French geologist, explored the Afar Triangle of Ethiopia for fossils. Their explorations revealed a fossil-rich area. In 1973, Johanson helped to organize the International Afar Research Expedition to explore a promising site in the Afar area. In October of that year, Johanson, leading the expedition, unearthed a fossilized knee joint that was dated as 3.5 million years old. The importance of the find lay in the proof it offered that human stature and bipedal locomotion dated from such early origins.

In 1974, Johanson returned to the Afar site. This time, he discovered a complete skeleton. The skeleton was the oldest known to anthropologists. He called the find "Lucy" after the hit Beatles' song "Lucy in the Sky with Diamonds." Analysis of Lucy showed that she was a biped that walked upright, and therefore she was not an ape, although she had an apelike brain. She was given the scientific name *Australopithecus afarensis* (that is, "Afar southern ape").

Johanson concluded that Lucy was the "missing link" to the common ancestor of humans and apes. Johanson's hypothesis, if sustained, would overturn the traditional theory espoused by the Leakeys that brain enlargement came before or at least with the development of bipedalism and tool making.

Johanson's interpretation of the theory of human evolution contradicts the theory espoused by the Leakeys. Specifically, Johanson rejected the theory of the Leakeys that humans descended from earlier members of the genus *homo*. He argued that humans descended from *australopithecines* of which Lucy is a representative.

In 1986, Johanson led an expedition to the Olduvai Gorge in Tanzania. That year he discovered a 1.8-million-year-old skeleton of the earliest of the direct ancestors of humans, *Homo habilis*.

JONES, WILLIAM (1746–1794)

Sir William Jones was a British polymath whose scholarly research and vision were critical to both modern linguistics and Indology. In his founding

of the Asiatic Society in Calcutta in 1784 and the journal *Asiatic Researches*, Jones set forth a broad, interdisciplinary program of research in Indian languages, religions, history, law, natural history, medicine, and botany that represent anthropology at its finest, and that deeply challenged colonial attitudes of the times.

Jones received a classical education in England, which he supplemented with studies of Arabic and Persian. In his early 20s, he became known for his translations from Persian poets and his grammar of Persian. He did not inherit wealth, so he supported himself as a tutor to the son of the Spencer family, and then studied law. His plan was to obtain a position as a judge in India where he could both conduct scholarly work and save enough money to support his later studies; however, Jones differed with the leadership in England on the American War—he was a friend of Benjamin Franklin—and so was relegated to work as a barrister riding legal circuits until the American War was over, when he finally received his appointment to the Supreme Court of Bengal, one of the three British-run provinces in India. He requested and obtained knighthood just before he left for India. His legal training and interest in comparative law were to affect his understanding of culture, presaging the importance of the comparative study of law for anthropology.

When his ship entered the Indian Ocean near the end of the 5-month voyage to India, Jones had a vision of the vastness of Asia, its sciences and arts, its great diversity and geniuses, all largely unexplored by Europeans. Jones arrived in India in 1783, and in early 1784 founded the Asiatic Society to begin to remedy this lack of knowledge through broad, interdisciplinary study. As Jones put it in his initial address to the Society, “Our objectives are Man and Nature: Whatever is performed by the one, or produced by the other.” A more succinct focus for anthropology is hard to imagine.

Jones saw that instead of just taking from India, the British could also make contributions through scholarship. He recognized the need for interaction among scholars and for cooperation and learning from local scholars. In colonial times, the thought that Europe could learn from India, let alone Indian scholars, was radical. Jones studied with local scholars on a daily basis, worked to have their research read at Asiatic Society meetings, and established an award for their finest work—all to encourage

cooperation and change in attitude among fellow Europeans.

It was Jones’s legal work in India that led to his study of Sanskrit. He believed that the local Hindus and Muslims should be tried according to their own laws and customs. Jones’s opinion lined up with the policy of the East India Company, which also understood non-interference in local ways to be in their best interest. But in carrying out local law, British justices were forced to depend on local pundits for understanding of Muslim and Hindu law, a practice which invited corruption. Jones’s knowledge of Persian and Arabic provided a sound basis for his scholarship on Muslim law, but for Hindu law he needed Sanskrit. In his first year in India he began study of classical Indian music and Hindu deities and texts, translated through Persian. When he finally decided that he must study Sanskrit himself, it was not easy, for many Indians did not think it appropriate for a Westerner to study their sacred language.

Jones was already fluent in 13 languages and competent in 28 others, yet Sanskrit, the last language he would study, held a special place for him. In his studies, he became aware of the excellence of Sanskrit phonetic description, ascribed to the Sanskrit scholar Panini. Yet Jones’s contribution would not be in descriptive linguistics, but rather in explaining the relation between many European languages, some Middle Eastern ones, and Sanskrit, a relation that was profoundly disturbing to ethnocentric Europeans of the time.

Jones noted the affinity of Sanskrit with the classical languages of Greek and Latin, and then explained this relationship as due to a common source that no longer exists. Earlier scholars had noted the similarities of Greek and Latin, as well as similarities of Germanic languages. Several scholars (Sasetti, 1585; Coerdoux, 1767) had also noted an affinity between Greek and Sanskrit, including Scottish Lord Monboddo (1774), an acquaintance of Jones. But it was Jones who first gave a clear explanation for the similarities, and who first described languages coming from a common source as a “language family.” The postulate of a common source language that no longer exists became known as a *proto-language*; the language family to which Sanskrit, Greek, and Latin belonged became known as the Indo-European language family. At the Third Anniversary Address of the Asiatic Society in Calcutta in 1786, Jones first presented this

research within the context of addressing the origins of the five main Asiatic peoples.

The Sanscrit language, whatever be its antiquity, is of a wonderful structure; more perfect than the Greek; more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could possibly have been produced by accident; so strong indeed, that no philologist could examine them all three, without believing them to have sprung from some common source, which, perhaps, no longer exists; there is a reason, though not quite so forcible, for supposing that both the Gothick and the Celtick, though blended with a very different idiom, had the same origin with the Sanscrit, and the old Persian might be added to the same family.

Jones's genetic model of language owes inspiration to the taxonomic work of Linnaeus, which Jones deeply admired. By the same token, Charles Darwin would later draw inspiration from Jones's explanation of the relationships of languages, and their implied mutability, in his theory of evolution and the relationships of forms of life. In the analogy between language and biology, language families are similar to genera, languages to species, dialects to varieties, and idiolects (the language form of an individual) to individual animals or plants.

A less well-known influence on Jones's analytical work in relating languages was his experience with evidence in the courtroom. This was a time when many still explained the multitude of languages in the world as a result of the Tower of Babel. Those not confined to literal interpretation of this Biblical story often confused *borrowings* with *cognates*. It is common for languages to borrow words from other languages in which they are in contact. But cognates show that the languages are indeed related. Notice the multiple types of evidence—"in the roots of verbs and the forms of grammar"—not just in separate words, in Jones's famous explanation from the Third Anniversary Address of the Asiatic Society. This careful use of evidence is the basis for all sound scholarship, and it informed Jones's work from translations to botany.

Overall, Jones's explanation of the relation of languages led to modern linguistics, specifically to what became known as historical or comparative linguistics, that flowered in the 19th century as scholars put

forward "laws" of phonological change in languages and classified other language families. Jones's design of broad, interdisciplinary research for the Asiatic Society of Bengal served as the prototype for systematic field research. And Jones's work as the first Westerner to write on classical Indian music, the first person to put forward a classification of Indian plants and animals, and his emphasis on the importance of study of Hinduism and Sanskrit, initiated the field that became known as Indology. His work in compendia of Muslim and Hindu law is important in the legal systems of South Asia to this day. For anthropology, Sir William Jones's work is a testament to the profound importance of the study of language in research.

JUSTICE AND ANTHROPOLOGY

Justice refers to the constant and perpetual disposition of legal matters or disputes to render every person his or her due. The concept of justice traces its origin to the Greek language. The Greek word "dike" corresponds to the idea of staying in one's assigned place or role. The Greek philosophers Plato and Aristotle developed definitions of justice. Plato believed that justice means maintaining society's order with each person performing his natural role. Aristotle described justice in terms of proportion and equality. Aristotle believed that justice means treating individuals with fairness, and it is a matter of distributing goods in their right proportion.

Although law and justice are related concepts, they have distinct definitions. Law, in its generic sense, is a

body of rules or action or conduct prescribed by a controlling authority and having binding legal force. Justice, on the other hand, emphasizes fairness and rights. It implies the moral and impartial treatment of all persons, especially by the legal system of a society. However, conceptions of justice may come into conflict with the legal system of a society. For example, legal scholars as well as social scientists now consider laws that supported slavery as unjust laws. Anthropologists and legal scholars also debate justice from the points of view of moral relativism and moral objectivism. Moral relativists argue that justice has different meanings in different societies and that what one society considers unjust may not have that meaning in another society. Therefore, the anthropologist must seek to understand the meaning of justice in a particular society. Moral objectivists argue that there are standards of justice that can be used to judge the treatment of persons in every society. While the traditional training of anthropologists criticized value-based anthropological research, more recently the field of anthropology encompasses many anthropologists who espouse a moral objectivist position and who criticize the treatment of persons in the society they are studying from a perspective of social justice.

Scholars also distinguish three major types of justice: *distributive*, *commutative*, and *corrective*. Distributive justice is concerned with analysis of the distribution of the benefits and burdens of society. Most discussions of distributive justice concern the measurements that societies use to allocate society's resources, such as need, rank, agreements, or merit. Commutative justice deals with how to achieve a fair resolution between individuals when people believe they have been wronged. The purpose of commutative justice is to render to a person what belongs to that person in such a way that no one gains by another's losses. Corrective justice is concerned with how people should be punished for wrongdoing. It seeks to define what is considered fair punishment and what is considered a fair process for determining guilt before imposing punishment.

Anthropologists typically examine justice from one of three paradigms: functionalism, conflict, or pluralism. The functionalist paradigm characterizes society as a community consisting of like-minded individuals. Functionalists view law as a unifying force in society because it is a tool for resolving disputes and achieving justice. The conflict perspective

relies on a Marxist conception of power, characterizing law as a tool of the powerful in society who want to maintain the status quo. Conflict theorists argue that the powerful write laws for their own benefit, resulting in the existing system of social inequality containing many laws that are unjust because they oppress the poor and other marginalized groups. The pluralistic paradigm seeks to provide a more complex understanding of justice issues in a society. Pluralists emphasize that justice is defined by interest groups in society, but these interest groups can change over time. This perspective also argues that interest groups may hold diverse ideas of justice that may be contradictory to one another.

Early anthropological studies of justice were largely conducted in non-Western societies and emphasized discovering the rules used to solve disputes. For example, Bronislaw Malinowski (1884–1942), studied the Trobriand Islands of Melanesia where he applied and discovered the importance of reciprocity, an exchange system based on mutual services between individuals and groups, as the basis for law, and consequently for social order. Malinowski posited that the obligations associated with reciprocity have the social function of safeguarding the continuity and adequacy of mutual services. He concluded that the obligations associated with reciprocity are the primary social bonds in Trobriand society.

In the 1970s, in addition to examining the rules used to resolve disputes, anthropologists also studied the processes by which disputes are resolved within the sociocultural context of a community. Through such observations, anthropologists learned that people often managed their legal disputes and arrived at a just outcome through a system of informal, negotiated settlements among parties rather than court-centered approaches. For example, Laura Nader used the concept "harmony ideology" to interpret her work on dispute resolution in a Mexican-Zapotec mountain village. Nader argued that the reason people presented themselves as resolving all disputes harmoniously was part of a political strategy to keep colonial authorities from meddling in village affairs.

In the 1980s, anthropologists continued to study justice from the perspective of dispute resolution; however, this research began to emphasize a concern with issues of stratification and power. Anthropologists also expanded their scope of inquiry to

include such concerns as the field of human rights, prisoners, migrants, refugees, and other issues. As they expanded their scope of inquiry, anthropologists examined how law as a system of meaning presents a social construction of the world as just; that is, law, as an ideology, is embedded in the cultural meanings of a society. More recently, this approach frequently examines justice issues within the context of globalization. For example, some anthropologists report persecutions and other atrocities of peoples. This includes analyzing the tension between local formulation of human rights and its global counterpart; i.e. the ideology of international human rights. In addition, some anthropologists will endorse a particular definition of human rights and they may identify the kind of political systems that can provide these rights. These anthropologists hope to contribute to the social construction of a just world.

KANT, IMMANUEL

Immanuel Kant was born on the 22nd of April, 1724, in Königsberg, Prussia (now Kaliningrad) and he died in the same city on the 12th of February, 1804. He was the fourth of nine children of his parents, Anna Regina, neé Reuter, and Johann Georg Kant, who both belonged to a Pietist branch of the Lutheran Church. When Immanuel Kant was eight, he entered the Pietist school, Friedrichskollegium, and remained there until 1740. As his parents were rather poor, he was dependent on financial support from Franz Albert Schultz (1692–1763), who had realized Kant's immense talent, and who was headmaster of Kant's school, professor of theology, and pupil of the famous German thinker of the Enlightenment, Christian Wolff (1697–1754).

Kant's mother died in 1737 while he was still at school. From 1740 to 1746, the year his father died, Kant attended the University of Königsberg, studying philosophy, mathematics, natural sciences, and theology. After university, Kant earned his income as a private tutor for three families in the area of Königsberg. In 1755, he completed both his doctoral degree (*Meditationum quarundam de igne succinta delineatio*), as well as his habilitation (postdoctoral qualification) thesis (*Principiorum primorum cognitionis metaphysicae nova dilucidatio*).

In autumn 1755, he started to lecture at the University of Königsberg, and he had to finance himself from the fees he received from his students. The first time Kant had a salaried post was in 1766 as a librarian. Later, he was offered various professorships (e.g., Erlangen, Jena), which he turned down. He had to wait until 1770, when he was already forty-six, to become Professor of Logic and Metaphysics at the

University of Königsberg. Eleven years later, Kant's groundbreaking work, *Kritik der reinen Vernunft* (*Critique of Pure Reason*, 1781) was released. Schopenhauer named it the most important book ever written in Europe; however, initial response was not so favorable. As a consequence, he wrote the *Prolegomena zu einer jeden künftigen Metaphysik* which was published in 1783, the same year Kant bought himself a house. In 1785 Kant published the *Grundlegung zur Metaphysik der Sitten*; in 1787 the second edition of the *Kritik der reinen Vernunft*; in 1788, the *Kritik der praktischen Vernunft*; and in 1790, the *Kritik der Urteilskraft*. In 1793, Kant published *Die Religion innerhalb der Grenzen der bloßen Vernunft*, and it was this work that brought him into conflict with state authorities who wished to censor the work. A year later, he even wrote a second treatise on the philosophy of religion, *Das Ende aller Dinge*. As a consequence, he received an official letter accusing him of degrading Christianity and violating his duties as a teacher of youth. Even though he rejected the accusations, he agreed to refrain from writing further works about the philosophy of religion. *Zum ewigen Frieden* (1795), was Kant's first book after his conflict with the authorities, and *Die Metaphysik der Sitten* was released in 1797. In *Anthropologie in pragmatischer Hinsicht* (1798), Kant published further material on the philosophy of religion since Friedrich Wilhelm II, who was mainly responsible for the intolerant political atmosphere, had died. In October 1803, Kant became seriously ill. He died on the 12th of February, 1804.

Reason

Reason is a faculty for gaining knowledge. Kant wrote critiques of aspects of reason in order to find out what can be known. In doing so, he did not condemn

Source: Courtesy of the Library of Congress.

reason, but rather determined its limits and sources. In the end, Kant rejected both empiricism and rationalism as appropriate theories of knowledge. There are purely rational ideas, but only as regulative principles, which means the ideas are connected to empirical data. Kant employed the following distinctions for his investigations: *a priori/a posteriori*; and *analytic/synthetic*. A priori judgments are judgments independent of empirical experiences. A posteriori judgments are judgments founded in empirical experiences. Analytic judgments are judgments in which the predicate is already contained in the subject. Synthetic judgments are judgments in which the predicate is not contained in the subject but provides further information about it.

According to Kant, reason has both a material and a formal aspect. The formal aspect of reason is concerned with laws of thinking irrespective of any object, or general logic. General logic does not have any material aspect, as it solely rests on the necessary laws of thinking, deals with analytic, a priori judgments and is constituted from two aspects: Analytics, by means of which one positively tries to describe what understanding is capable of; and dialectics, by

means of which one tries to rule out what reason is not able to achieve. Reason, in its narrower sense, is the highest source of knowledge, and it brings together whatever has already been structured by means of our understanding to establish the highest unity of thinking. Understanding also belongs to the higher sources of knowledge, but has a common root with sensibility. In addition, it is capable of structuring and linking anything given to it, and of establishing laws.

The material aspect of reason, on the other hand, deals with objects and the laws by which they interact. These laws are either laws of nature or laws of freedom. The science that deals with the laws of nature is called physics, whereas the science which deals with the laws of freedom is referred to as ethics. Both physics and ethics have empirical as well as nonempirical aspects. Whatever is nonempirical is rational and valid a priori, and all areas with which rational investigation is concerned are called types of metaphysics. In contrast to general logic, which deals with analytic, a priori judgments, metaphysics is supposed to help promote knowledge; it deals with synthetic, a priori judgments. However, it is far from obvious whether such judgments are possible. Consequently, Kant asked in his *Kritik der reinen Vernunft*, how are synthetic judgments a priori possible?

In his transcendental *Elementarlehre* (teaching of the main elements) Kant answered his question. His *Elementarlehre* addresses transcendental aesthetics, the transcendental logic wherein one can distinguish the transcendental analytic, and the transcendental dialectic. Aesthetics encloses the realm of the senses; analytic, the realm of understanding; and dialectic, the realm of reason. Within his transcendental aesthetics, Kant articulated that all sense perceptions must be structured within space and time as pure forms of intuition. Within his transcendental analytic, he explained that all thinking must be based upon the categories of, for example, causation. These are two of Kant's most influential insights.

As both physics and ethics have rational aspects, there is a metaphysics of nature (physics deals with laws of nature) and a metaphysics of morals (the nonempirical aspect of ethics is referred to as moral philosophy). Theoretical reason deals with the metaphysics of nature. There is an analytics of pure theoretical reason which progresses from sensual experiences to notions and then to principles. Practical reason

deals with the metaphysics of morals. There is an analytics of practical reason which progresses from the possibility of practical principles a priori to the notion of the objects of practical reason to moral feelings. Analytics is always concerned with notions (both of nature and of freedom) and principles. As a side note, rational investigations concerning the existence of God, the soul, and free will are impossible, according to Kant, as these things are beyond sense perceptions, and if one applies human forms of sensual perception (time and space) and human forms of thinking (e.g., causation) to things which are beyond sensual experience, one is led into contradictions.

Areas of study concerned with the empirical aspect of physics are now referred to as natural sciences. The empirical aspect of ethics is called practical anthropology. In practice, practical anthropology is the empirical investigation into all ethical questions. One must not forget that all laws, finally, are one aspect of reason. The formal aspect of reason deals with the laws of logic, and the material aspect of reason with laws of ethics and physics. One of the early Platonists, Xenokrates was the first to distinguish philosophy into categories of logic, ethics, and physics. This distinction played a vital role for Platonists and Stoics. Kant's ethics owe a lot to Cicero's, who in his final phase held a traditional Stoic position.

Kant distinguished between empirical and rational ethics. Empirical ethics is mostly practical anthropology; rational ethics, or the metaphysics of morals, is a rational investigation of moral law. The central aspect of the moral law is the will, as the will is responsible for one's acts. The will constitutes character, which can be good, evil or holy. Ethics is concerned with the law of freedom, for without the realm of freedom, human choices would be determined solely by drives or natural instincts as all animals are. Since human beings also belong to the realm of freedom or reason, reason decides when to act according to instinct and when to act according to reason. As humans belong to both realms, it is impossible not to be affected by one of them. All humans act sometimes according to reason, and sometimes according to instincts. Whether the will can be referred to as good or evil depends on which aspect is dominant. If a person acts mainly according to reason, then the will is good, if not, then it is evil. The moral law or the law of freedom has to be a law of duty, as individuals always have the inclination to act according to instinct and must force themselves to act according to reason. Once the

inclination to act according to instincts is absent, the will is holy.

An individual acting according to reason bases actions on moral law which can be determined by the categorical imperative whose general formulation is, "Act so that the maxim may be capable of becoming a universal law for all rational beings" (Note: A maxim is the determining motive of the will). Each act that, if taken as a general rule, leads, for example, to the extinction of humanity, or to self-contradiction, does not fulfill the demands of this imperative. It is an imperative, as individuals are not inclined by instinct to act in accord with it. It is categorical, because it is unconditionally valid. Kant also mentions the hypothetical imperative that refers to all conditional connection without the end being a necessary one. If one wishes x, one has to do y, without y being a necessary motive for all rational beings. The moral law encloses the categorical imperative only.

To be able to base one's actions on the moral law, or to be autonomous—which is the same—is the reason for a being to have dignity. All rational beings can base their acts on the moral law, and all human beings are rational. Therefore, all human beings have dignity. In the realm of purposes, every thing either has a price, or dignity. That which has a price does have something that is its equivalent: It can be exchanged for something else. That which has dignity, on the other hand, is beyond all price; therefore, Kantian ethics exclude the possibility of calculations which are basic for a utilitarian. In utilitarianism, it can be justifiable for one person to kill another in order to save the life of a hundred, but Kantian ethics hold the dignity of one person as beyond all price.

As all rational beings have such dignity, one might wonder from what point a human being is rational. Rationality is linked to the capacity for making abstractions, forming concepts, and having a language. One might be tempted to infer that human beings achieve rationality around the age of three; however, Kant asserted that rationality is part of the immortal soul of a human being. Therefore, human beings already are in the possession of rationality before their bodies are able to express that capacity. Around the age of three, the body is able to express that capacity, but human beings are already rational from the time their bodies and souls are united. All these discussions are particularly relevant for the current bioethical debates, as dignity is a fundamental

part of many current constitutions, and Kant's concept of dignity is the most popular one.

KARDINER, ABRAM (1891–1981)

Abram Kardiner was a psychiatrist and pioneering psychoanalyst who made major contributions to psychological and psychoanalytic anthropology as well as to his own professions. He was particularly interested in the psychological adaptation of the ego to war, society, oppression, and culture. Kardiner is best known in anthropology for his concepts of *basic personality structure* and *projective systems*.

Kardiner was born in 1891 in New York City. He received a BA from City College (New York) in 1912, then completed a year of medical school at Cornell University. He entered the PhD program in anthropology at Columbia University, studying under Franz Boas and Alexander Goldenweiser for a year before returning to finish his MD at Cornell in 1914. Kardiner completed his internship and residency in psychiatry in New York City and joined the New York Psychoanalytic Society. In 1921 he went to Vienna for a six-month training analysis with Sigmund Freud, and also took the opportunity to attend lectures by Geza Roheim on psychoanalysis and anthropology. On his return to New York, Kardiner worked for a veterans hospital in the Bronx from 1922–1925, studying victims of “war neuroses” from World War I. He published *The Traumatic Neuroses of War* in 1941 and an updated version, *War Stress and Neurotic*

Illness, in 1947. Kardiner is now credited with defining posttraumatic stress disorder (PTSD).

Kardiner co-founded the New York Psychoanalytic Institute in 1931, the first such training institute in the U.S. In 1933, the director, Sandor Rado, asked Kardiner to develop a course on the application of psychoanalysis to the study of culture. The first session had only two students, but the seminar eventually grew to a hundred and included many distinguished anthropologists. The standard practice was for an anthropologist to describe a culture; Kardiner would then analyze it in terms of his neo-Freudian ego psychology.

Ralph Linton came to Columbia in 1937 to replace Boas as chair of the anthropology department. Linton was introduced to Kardiner by the psychologist Abraham Maslow, who was a participant in the seminar and a former student of Linton. Linton joined the seminar and presented his studies of the Marquesans of the South Pacific and the Tanala and Betsileo of Madagascar for Kardiner's analysis.

Kardiner published his major contribution to anthropology, *The Individual and His Society* in 1939, with Linton as a contributor. This comprehensive, causal theory of the relationship between culture and personality is regarded by some as the seminal work in the “culture and personality” movement that eventually gave rise to the field of psychological anthropology, providing the theoretical basis for much cross-cultural research in the postwar years, beginning with *Child Training and Personality* by Whiting & Child (1953).

Kardiner postulated the existence of a basic personality structure (BPS) personality traits shared by members of a society as a result of common early experiences. This BPS included unconscious conflicts and anxieties that motivated behavior. He divided culture into primary institutions, which generated the BPS, and secondary institutions, which were expressions of the BPS. The primary institutions included older, more stable elements of a culture such as technology, economics, family structure, and child-training practices, while the secondary institutions included religion, ritual, folklore, mythology, taboos, and art. Secondary institutions were based on the psychological process of projection and served to satisfy unmet needs symbolically. Basically, Kardiner posited a congruence between childhood experiences and expressive culture, mediated by the BPS, the same kind of congruity that Freud identified between parents and gods in *The Future of an Illusion*.

One problem Kardiner encountered was the availability of cultural, but not psychological data on the societies investigated. Cora DuBois was a postdoctoral student studying with Kardiner in 1936–1937. In 1938, DuBois went to the island of Alor in the Dutch East Indies to conduct ethnographic fieldwork, gathering dreams, autobiographies, word associations, children's drawings, and intelligence and projective tests. DuBois's fieldwork provided a model for culture and personality fieldwork for the next decade or more. Upon her return to New York, DuBois's data were analyzed by Kardiner as well as by two psychologists. Kardiner saw the results as confirmation of his theory of a shared personality. But in her classic ethnography, *The People of Alor* (1944), which included chapters and sections by Kardiner, DuBois replaced the concept of basic personality with *modal personality*, referring to central tendencies in the personalities of members of a society that are not necessarily shared by all.

Kardiner's work was not well received by his colleagues at the Psychoanalytic Institute, and in 1939 he brought the seminar to the Department of Anthropology at Columbia, where it was called "Psychological Analysis of Primitive Cultures." In 1944, Kardiner left the Institute to become a clinical professor of psychiatry at Columbia and the cofounder of what became the Center for Psychoanalytic Training and Research.

In 1945, Kardiner published *The Psychological Frontiers of Society*, a further explication of his BPS theory, with analyses of the Comanche (studied by Linton), the Alorese (studied by DuBois), and Plainville, a small town in the Missouri Ozarks (studied by James West, a pseudonym for Carl Withers).

During World War II, Margaret Mead, Ruth Benedict, and others turned their attention to the psychology of the British, the Japanese, and other modern peoples, beginning the study of "national character," which Kardiner found superficial. After the war, Linton left Columbia, and Kardiner moved his seminar to the sociology department.

Kardiner sought to demonstrate the applicability of his BPS theory to modern, complex American society with the publication in 1951 of *The Mark of Oppression: A Psychological Study of the American Negro*, written with Lionel Ovesey. This study involved four years of intensive research with 25 individuals, and it identified common personality dynamics that

African Americans had developed, according to Kardiner, to cope with discrimination.

In 1954, inspired by the Kinsey Report, Kardiner wrote *Sex and Morality* with Edward Preble. He returned to the subject of anthropology in 1961 with *They Studied Man*, a study of the beginnings of cultural anthropology that focused on the lives of ten scholars and the ethos of the times. His last book was *My Analysis with Freud: Reminiscences*, in 1977. Kardiner died in 1981 at the age of 90.

KEITH, SIR ARTHUR (1866–1955)

During his era, Sir Arthur Keith was one of the world's most prominent anatomists and defenders of Darwinism. As Keith himself noted in his autobiography, he seemed fated to espouse causes and theories that fail to carry conviction, a notion that became even more accurate than he realized when he wrote it in 1947.

Arthur Keith was born on February 5, 1866, in Old Machar in Aberdeenshire, Scotland. His father was John Keith and his mother, Jessie, was from the Macpherson family, also from Aberdeenshire. The family was sufficiently prosperous for Arthur to receive a good education at Gordon's College and Marishal College at Aberdeen University, where he graduated with first-class honors in 1888. Keith did

postgraduate study at Leipzig before spending three years in Thailand, officially on business for a rubber company, but also to collect botanical specimens for Kew. While in Thailand, Keith studied the musculature of the native monkeys; his thoroughly documented work earned him a medical degree in Aberdeen, as well as the Struthers anatomy medal in 1894, and remained influential for decades to come. During this period, Keith also did groundbreaking research in malformations of the heart.

From 1895 until 1908 Keith taught anatomy at London Hospital Medical College. He was a popular and effective teacher, and he wrote what became the standard textbook for the subject, *Human Embryology and Morphology* (1898), released in six editions. In 1908 Keith moved on to the important post of Conservator of the Hunterian Museum of the Royal College of Surgeons, a position he held until he retired in 1933. At the Hunterian, he set himself the task of reviving the scientific element of the College's program, both by his own lecturing and publishing, and by his ability to attract respected colleagues to associate with the College. He also attracted some major anatomical collections.

During his tenure at the College, Keith turned his attention away from anatomy to broader issues surrounding human evolution, in particular the question of the origin of different races. Keith achieved international prominence through championing the greatest of his lost causes, Piltdown Man. While not in a position to have originated the hoax himself, Keith did become one of Piltdown Man's most important advocates. In *The Antiquity of Man*, published first in 1915 and followed by seven impressions (two of them revised editions) Keith argued the case for Piltdown Man. He recognized fully the problems raised by the human-like skull and the simian mandible, as well as the difficulty in finding credible material of that age at the Piltdown site. But each problem was confronted honestly, relevant evidence was brought to light, and solutions were found. Keith was convinced not only that Piltdown Man was genuine, but also that he represented a common ancestor to *Homo sapiens* and Neandertal, which could be traced to the Pliocene. The only question Keith did not ask was whether the Piltdown findings were a hoax. Keith knew all the main players in the Piltdown affair and respected the professional integrity of each of them, even if his relations with Grafton Elliot Smith were strained.

Keith's last major contribution to anatomy was his work during World War I on the treatment of soldiers' wounds. His work in this area was published in 1919 as *Memoirs of the Maimed*, and it was reprinted in 1952.

As Keith approached retirement, he masterminded his last major project. Working with influential friends, Keith oversaw the creation of the Buckston Browne Research Farm at Downe, the village in Kent where Charles Darwin spent the greater part of his life. Keith and Browne (1850–1945) were also instrumental in converting Darwin's house at Downe into a museum. When Keith retired from the Royal College of Surgeons in 1933, he and his wife moved to Downe, taking over management of the research farm and writing.

Much of Keith's writing during the second half of his life was concerned with popularizing evolution for nonspecialist readers. In this he had the enthusiastic support of his friend Charles Albert Watts (1858–1946), founder of Watts & Co. publishers and chairman of the Rationalist Press Association (RPA). Keith had been brought up a Christian, but his science training slowly eroded those beliefs. By 1925 when he first spoke publicly on religious issues, Keith was a naturalist and an agnostic. He became an Honorary Associate of the RPA in 1923 and was active in the organization for the rest of his life. When Watts & Co. decided to publish a series of works of popular science called the Forum Series in 1926, Keith supplied four titles, more than any other contributor: *Concerning Man's Origin* (1928), which included Keith's 1927 presidential address to the British Association; *Darwinism and What It Implies* (1928); *The Construction of Man's Family Tree* (1934); and *Darwinism and Its Critics* (1935).

Keith was a regular contributor to the *Literary Guide* (the RPA journal), and all of the books written during the last three decades of his life were published by Watts & Co. The major titles included *A New Theory of Human Evolution* (1948), *Autobiography* (1950), and *Darwin Revalued* (1955). *A New Theory of Human Evolution* featured another of Keith's lost causes: the so-called amity–enmity principle of race competition as a feature of human evolution. Not surprisingly, the *New Theory* was reviewed positively in South Africa, but the irony was that Keith was not a white supremacist. While stressing the differences of the races, he never spoke in terms of superiority or inferiority. Keith dismissed white supremacism as “self

flattery.” The amity–enmity principle can be traced to his 1930 Rectorial Address at Aberdeen University when he spoke of war as nature’s pruning hook. But once again, Keith was neither a Lamarckian, nor a Social Darwinist, at least not in the cruder sense of the term.

KENNEWICK MAN

On July 28, 1996, the random discovery of a skull on the banks of the Columbia River near Kennewick, Washington changed the climate of archaeology. Discovered by two teenagers and initially examined by James Chatters, forensic anthropologist, this skull had many characteristics indicating its Caucasian origin. Characteristics of the skull’s teeth, however, suggested an extremely old specimen (around 5,000 years). Finding bones with Caucasian characteristics is not an unusual occurrence; however, potential dating of the bones to precontact times is certainly uncommon in North America. This incongruity became more pronounced after the recovery and examination of the remaining skeletal elements.

The analysis of the almost-complete skeleton suggested that the bones belonged to a 40- to 50-year-old male with Caucasoid features who was approximately 5 feet, 9 inches tall and had sustained injuries throughout his life. In his right pelvis was embedded

a projectile point resembling those manufactured and used by the people who inhabited the Columbia Plateau between 4,500 and 9,000 years ago. This puzzle became increasingly difficult for Chatters to solve; as a result, he decided to send a small piece of bone for radiocarbon dating in order to get a better sense of the age of the skeleton. The results of the radiocarbon dating came as a shock, making “Kennewick Man” one of the oldest skeletons in North America and beginning a seemingly never-ending battle over the specimen.

Because Kennewick Man was discovered on a portion of the Columbia River that is federal land maintained by the United States Army Corps of Engineers, the Native American Graves Protection and Repatriation Act (NAGPRA) came into play. NAGPRA was signed into law in 1990; it essentially states that if human remains are found on federal lands and their cultural affiliation can be established, those remains and associated grave goods must be returned to the affiliated tribe. The same portion of the Columbia River is also considered to be part of traditional homeland by the Umatilla tribe, as well as several other tribes in the area. As a result, by September of 1996, five tribes (Umatilla, Yakama, Nez Perce, Colville, and Wanapum) had jointly made a formal claim to the Kennewick Man skeletal remains. At this point, scientific study of the skeleton was halted. The Army Corps of Engineers took possession of the skeleton and announced intended repatriation of the bones to the alliance of tribes.

In October of 1996, eight well-known scientists sued to gain access to the Kennewick Man remains. Citing civil rights violations, a lack of due process, and the lack of definitive affiliation with any single Native American tribe (especially given the presence of several traits more consistent with Europeans), these scientists argued the necessity of studying the skeleton in order to determine ancestry and to allow the entire American public access to knowledge about its past. For the Native American tribes, Kennewick Man represented an ancestor, whose bones are sacred and who deserved reburial; for archaeologists, the skeleton represented a piece of potentially significant information in ongoing research on the peopling of the North American continent.

Several theories exist regarding the peopling of the New World. Evidence places humans in the New World 12,000 years ago. One popular theory posits humans coming across the Bering Strait into Alaska and journeying south through an ice-free corridor into the Plains area of North America. Recently, sites

and artifacts dating to earlier than 12,000 years have been discovered in eastern North America and in South America. This new evidence suggests the possibility of several different migrations of humans into the New World, potentially from parts of the world other than northern Asia and possibly earlier than researchers have previously assumed. Skeletal remains from these very early periods are rare; the completeness and ancient date of the skeleton make Kennewick Man a potentially important clue to increasing our knowledge about the earlier inhabitants of the North American continent.

For almost eight years, the battle continued over Kennewick Man. Before any ruling was entertained, Justice John Jelderks, Justice Magistrate of the United States District Court in Portland, Oregon, ordered the study of the skeleton to determine cultural affiliation. In October of 1999, the cultural affiliation report indicated that Kennewick Man was not similar morphologically to modern Native Americans or as close to European Americans as was initially presumed; rather, Kennewick Man most closely resembled populations from southern Asia, specifically, groups of Polynesia and the Ainu of Japan.

Multiple reports assessing cultural affiliation, coupled with extensive testimony, led to a ruling in

August, 2002, stating that scientists should be allowed access to the skeletal remains, and that the remains were not to be repatriated. Jelderks argued that in order for present-day tribes to claim skeletal remains or associated funerary objects, they must be able to establish a direct relationship with the skeletal remains. Jelderks argued that no such relationship was established for Kennewick Man and the tribes requesting repatriation of the remains. By the end of October, 2002, the tribes and the federal government had appealed the ruling of Justice Jelderks and, in the early part of the following year, the 9th U.S. Circuit Court of Appeals blocked the study of the skeletal remains pending their final decision.

In 2004, the battle seemingly came to an end when the 9th U.S. Circuit Court of Appeals upheld the decision made by Judge Jelderks in 2002. The ruling noted that a relationship between Kennewick Man and the tribes involved in the case was not adequately established. The ruling further indicated that the language of NAGPRA requires human skeletal remains to bear a relationship to a present-day tribe or culture; it also emphasized that the purpose of NAGPRA would not be served if the law ensured repatriation of remains to Native American groups without an established relationship to those remains. A proposed rehearing was rejected and the federal government declined to appeal the decision further.

While the Kennewick Man case appears to have been closed, it unearthed several deep-rooted issues. In *Skull Wars: Kennewick Man, Archaeology, and the Battle for Native American Identity*, David Thomas explains, “The multicultural tug-of-war over Kennewick Man raises deep questions about how we can make the past serve the diverse purposes of the present, Indians as well as white. It also challenges us to define when ancient bones stop being tribal and simply become human.”

KENYANTHROPUS PLATYOPS

One of a rash of new extinct hominid genera discovered and described during the turn of the 21st century, *Kenyanthropus* immediately garnered substantial press coverage and an onslaught of criticism after its naming in 2001. Characterized by its describers as a distinct genus that suggested a more complex early evolutionary history of the human lineage, this taxon was later dismissed by other researchers as either belonging to *Australopithecus* or *Homo*. Regardless of their taxonomic placement, the specimens described as *Kenyanthropus* exhibit a mosaic of primitive and derived characters that may help elucidate the characteristics, habits, and environments of human ancestors.

Kenyanthropus was described in 2001 by Meave G. Leakey, Fred Spoor, Frank H. Brown, Patrick N. Gathogo, Christopher Kiarie, Louise N. Leakey, and Ian McDougall. Fossils belonging to the type species *Kenyanthropus platyops* were discovered at the Lomekwi Site in Kenya, on the western side of Lake Turkana, during a series of expeditions from 1998–1999. Over 30 hominid fossils were uncovered during the field sessions, two of which were described as *K. platyops*. These specimens were found in the Pliocene Nachukui Formation, indirectly radiometrically dated as 3.5 million years old. The holotype, discovered by Justus Erus in August 1999 and denoted as KNM-WT 40000, is a largely complete, yet heavily distorted cranium lacking most of the cranial base and the premolar and anterior tooth crowns. The paratype, KNM-WT 38350, is a partial left maxilla found by B. Onyango in August 1998.

Leakey and co-authors recognized that the overall size of the holotype fell within the size range of *Australopithecus afarensis* and *A. africanus*, but erected a new genus based on the cranium's mosaic of primitive and derived characters. These derived characters include a flat face, a condition known as orthognath; a tall cheek region; and small molars. Of these characters, the orthognathic facial morphology of *Kenyanthropus* is most unique. While other extinct hominids, including *Paranthropus*, possess such a morphology, only in *Kenyanthropus* is an orthognathic face associated with small molars. In addition, *Kenyanthropus* shows the earliest evidence of orthognath in the hominid fossil record. Despite these advanced features, *Kenyanthropus* also displays many primitive traits shared with australopithecines, including flat nasal margins and a small brain that compares in size with those of chimpanzees. Interestingly, *Kenyanthropus* shares many characters with *Homo rudolfensis*, including the lack of a depression behind the brow ridge and a flat plane beneath the nose bone. These characters may indicate that *Kenyanthropus* is a close relative, possibly an ancestor, of modern humans, and has led to the suggestion that *H. rudolfensis* be transferred to the genus *Kenyanthropus* (as *K. rudolfensis*).

Aside from providing important anatomical information, the discovery of *Kenyanthropus* added to the diversity of the eastern African hominid record of 3–4 million years ago, which had previously been represented solely by *A. afarensis* and *A. anamensis*. Additionally, the unique combination of derived and primitive characteristics indicated that *Kenyanthropus* had evolved a specific diet, and pointed to a diet-driven radiation early in the history of the human lineage. Based on this evidence, Leakey and her co-authors argued that human evolution didn't follow a well-defined path, with a continuum of species leading to *Homo sapiens*, but instead took the form of a "bush," with many unique species branching off at various points. Coupled with the discovery of other genera announced at roughly the same time, such as *Orrorin*, *Sahelanthropus*, and *Ardipithecus*, this interpretation of *Kenyanthropus* and its implications for human evolution diverged sharply from traditional views that advocated a "straight-line" path to modern humans.

However, other researchers have disagreed with the views of Leakey and her co-workers. Paleoanthropologist Tim White argued that the holotype cranium of

Kenyanthropus was too distorted to allow proper comparison to other hominid fossils. He noted that a geological process called Expanding Matrix Distortion (EMD) heavily damaged the cranium and resulted in its breaking into some 4,000 separate pieces. Since EMD doesn't enlarge or distort all dimensions equally, it commonly leads to an indecipherable complex of deformation that is often impossible to correct for, thus making precise identification tenuous. Since comparison to other fossils is made difficult by EMD, White argued that it is impossible to differentiate *Kenyanthropus* from the contemporaneous *A. afarensis* and *A. anamensis*, especially considering the known cranial variation in modern apes and humans. As a result, he opted for a conservative taxonomy that sunk *Kenyanthropus* into *Australopithecus*.

Camilo J. Cela-Conde and Francisco J. Ayala have suggested a different placement for *Kenyanthropus*. Unlike White, they recognized the distinct features of *Kenyanthropus* as real, and not a product of deformation. However, they contended that the similarities between *Kenyanthropus* and *Homo rudolfensis*, including smaller molars and thinner tooth enamel, were indicative of a close phylogenetic relationship. Therefore, they advocated that *Kenyanthropus* be included in the genus *Homo*, likely as its earliest known species. Their proposal placed the appearance of *Homo* at 3.5 million years ago.

Regardless of the uncertain taxonomic placement of *Kenyanthropus*, the discovery of the holotype and paratype, along with representatives of their associated flora and fauna, are revealing new insights regarding the environments and life strategies of human forebearers. Geological evidence preserved at the Lomekwi Site indicates that the area was wet and heavily vegetated during the time of *Kenyanthropus*. The discovery of certain bovid fossils suggests a mosaic of woodland and forest habitats, which argues against the common hypothesis that much of human evolution was driven by a sudden environmental shift between forests and savannas. Additionally, the paleo-environment of the Lomekwi Site is similar to the few known hominid sites of similar age, including Laetoli in Tanzania, Hadar in Ethiopia, and Bahr el Ghazal in Chad.

While only a preliminary description of its bones has been published, *Kenyanthropus* is regarded as being among the most intriguing and informative of a handful of new hominid genera described during the close of the 20th century and the dawn of the 21st.

Although some arguments remain over the validity of these new taxa, their discoveries are proof that much about human evolution remains to be discovered.

KENYAPITHECUS WICKERI

Long recognized as an important genus for understanding the ancestry of great apes and humans, *Kenyapithecus* has been the subject of fierce taxonomic debate since its original discovery by noted paleoanthropologist Louis Leakey in 1961. Once seen as a direct ancestor of modern humans, *Kenyapithecus* is currently viewed as lying close to the origin of the great ape-human clade; however, controversy over the taxonomy and phylogeny of this genus continues, with researchers commonly arguing over the proper relationships of the two included species, *K. wickeri* and *K. africanus*.

Although fossils of *Kenyapithecus* are limited to isolated teeth, facial material, and other fragmentary bones, this primate is recognized as the most common large-sized hominoid known from the Middle Miocene of Eastern Africa. Louis Leakey discovered the first remains of this genus in 1961 when he excavated an upper jaw and isolated teeth from the 14-million-year-old sediments of Fort Ternan in western Kenya. One year later he described these specimens as *Kenyapithecus wickeri*, which he reconstructed as an early direct ancestor of man. In 1967 Leakey named a second species, *K. africanus*, which he based on fragmentary teeth and jaw material found at Maboko

Island in Lake Victoria, 100 kilometers from the Fort Ternan site.

The discovery and description of both *Kenyapithecus* species drew the attention of the paleoanthropological community, and several additional excavations were launched in western Kenya in hopes of finding new material. These excavations recovered numerous important new specimens, many of which proved controversial. In the years immediately following Leakey's early descriptions, it was commonly argued that *Kenyapithecus* was identical to *Ramapithecus*. While this view has fallen out of favor, few modern researchers support the validity of *K. africanus*. Based largely on the discovery of a nearly complete skeleton unearthed in the Tugen Hills in 1993, a team of scientists led by Steve Ward has advocated the transfer of *K. africanus* to its own genus, *Equatorius*; however, this proposal has also garnered debate, as other researchers have argued for a link between *K. africanus* and *Griphopithecus*. This taxonomic debate has yet to be settled, but regardless of the arguments, most researchers view *Kenyapithecus wickeri* as lying close to the origin of the great ape-human clade, and *Equatorius* (*K. africanus*) as a more primitive form.

Much of the aforementioned taxonomic debate can be blamed on the fragmentary nature of the known *Kenyapithecus* fossils, which are mostly limited to teeth and facial bones. Postcranial remains, which are often most phylogenetically informative, are poorly known; hence much about the anatomy and habits of *Kenyapithecus* are questionable. Based on the limited material, however, *Kenyapithecus* is known to have been a large, sexually dimorphic hominoid characterized by a robust lower jaw and thickly enameled teeth. These dental features have suggested to some researchers that *Kenyapithecus* fed on hard or abrasive foods such as nuts and coarse fruits.

Substantially more anatomical information is known for *Equatorius* (*K. africanus*). Based on the 1993 skeleton, which at the time of its discovery was the first Middle Miocene hominoid fossil preserved with associated teeth and postcranial remains, Ward and his coworkers have determined that *Equatorius* is more primitive than *K. wickeri*. Additionally, they have suggested that *Equatorius* was semiterrestrial, and thus the earliest known ape to occasionally leave the treetops for the ground. This transition, which was later paralleled in the immediate ancestors of humans, occurred about 15 million years ago when

the rain forests of Africa were gradually replaced by open woodland. This environmental change may also explain the specialized diet of *K. wickeri*, which lived about one million years after *Equatorius*.

Fossils of *Kenyapithecus* and *Equatorius* have also been used as key evidence to support the controversial "Return from Eurasia" hypothesis which posits that hominoids went extinct in Africa during the Early-Middle Miocene while simultaneously diversifying in Eurasia. Later, during the Middle-Late Miocene, these Eurasian hominoids, which included the direct ancestors of the great ape-human clade, returned to Africa, where they subsequently evolved into modern great apes and humans. The ages of *Kenyapithecus* and *Equatorius*, along with their similarities to taxa known from Europe and Asia and the dearth of hominoids from the Middle-Late Miocene in Africa, have been used to support this hypothesis. Other researchers have argued that this scarcity of hominoid fossils is the result of an imperfect fossil record, and that the dating techniques used by the proponents of the reentry hypothesis are imprecise. Ward and his colleagues argue against this hypothesis, but do support a linkage between *K. wickeri* and a currently unnamed species known from the Middle Miocene site of Paşalar, Turkey. This connection, which is manifested by similarities in canine and incisor morphology, represents the earliest known link between African and Eurasian Miocene large hominoids; however, Ward and his colleagues view this linkage as indicative of an African-Eurasian migratory relationship, not a full-scale extinction and reentry event.

The fossil record of African Middle-Late Miocene hominoids has long been recognized as representing a transition from species retaining primitive characteristics to more derived forms, including several species close to the origin of the speciose great ape-human clade. Although it was originally described as a hominid closely related and perhaps directly ancestral to humans, *Kenyapithecus* is now viewed as either a primitive member of the great ape-human clade or a genus lying immediately outside it. Largely due to the dearth of fossil material, *Kenyapithecus* jumps around many modern cladograms, but paleoanthropologists recognize this controversial genus as important for understanding the early evolution of many human characteristics.

 KETTLEWELL, H. B. D. (1907–1979)

Henry Bernard Davis Kettlewell, MD, an outstanding physician, lepidopterist and geneticist, is best known for his work on industrial melanism that so elegantly illustrates evolution in action it is now a feature of almost all basic biological texts. Kettlewell was also an energetic field researcher and co-founder of the significant Rothschild-Cockayne-Kettlewell Lepidoptera Collection in the British Museum.

Kettlewell was born on February 24, 1907 in Howden, Yorkshire, UK. He was a schoolboy at Charterhouse, trained in medicine and zoology at Gonville & Caius College, Cambridge, and then was a postgraduate clinical trainee at St. Bartholomew's Hospital, London. He later practiced general medicine as well as anesthesiology before service at Woking War Hospital. In 1949, he immigrated to the University of Cape Town, where he initiated research and from which he took expeditions to the Kalahari, Knysna Forest, Congo, and Mozambique. In 1952 he repatriated as a Nuffield Research Fellow in Genetics and Zoology at Oxford. In 1958 he led an expedition to Brazil marking the centennial of Darwin's *Origin of the Species*. From 1965 on, he was a Fellow of Iffley (now Wolfson) College, Oxford. Kettlewell died in 1979 of an accidental overdose.

In Britain prior to the industrial revolution, *Biston betularia* was a common moth of which a light-colored *typica* form predominated. A new, dark-colored phenotype—*Biston betularia carbonaria*—was first reported in 1848; remarkably, by 1895, this novel

type comprised 98% of populations near Manchester. Such dramatic increase in *carbonaria* subspecies caused many to deduce that this was due to deposition of black coal soot throughout the landscape, notably on tree bark.

Manifestly, *carbonaria* is easiest to see against a light background but nigh invisible on a dark background; the reverse is true of *typica*. Indeed, *typica* was more commonly seen in the country, whereas *carbonaria* was more commonly seen in besooted urban areas. Moreover, with the advent of modern, antipollution practices, there has been a marked decline in environmental soot and, simultaneously, a sharply reduced frequency of *carbonaria*. In fact, some lepidopterists worry *carbonaria* will soon be extinct.

For decades it was widely assumed that the rise and decline of *carbonaria* evidenced evolution in action; however, Kettlewell, seeking empirical proof, embarked on his classic research in the 1950s. His results confirmed the hypothesis that camouflage congruent with the usual landscape surfaces on which the moths often alit was an essential driving force via natural selection. In 1998, geneticist Michael E. N. Majerus of the University of Cambridge reviewed the original studies of melanism by Kettlewell and others. Majerus endorsed Kettlewell's basic finding that phenotype color directly affected differential moth survival. Majerus also reported that many experiments—including some of Kettlewell's—were either not rigorous enough or not properly designed. For example, one main study compared predation of moths congruent and noncongruent with tree trunk bark coloration, but the moths do not often perch on tree trunks. Likewise, control for both the ultraviolet visual acuity of predator birds and the effects of migration was not adequate. Unfortunately, Majerus's review has been much misconstrued—sometimes rather polemically—by nonspecialists and creationists among others. Kettlewell's work remains a paragon of excellent field study.

Kibbutz (plural: kibbutzim) is the Hebrew word for communal settlement, and it refers to a particular type of rural community in Israel. The basic principles on which the kibbutz is based are joint ownership of property, social and economic collectivism, cooperation in production, direct democracy, egalitarianism in work, and voluntarism. While initially agriculturally based, most kibbutzim have expanded into small industries as well (e.g., metal work, plastics, processed foods). Some have also expanded into tourism and recreational facilities. Many kibbutzim run study courses for the integration of new immigrants to Israel, focusing on intensive Hebrew language instruction, lectures on Israeli culture, and tours of the country. Although each kibbutz is an independent entity, national federations have formed to coordinate activities and facilitate cooperation between kibbutzim.

The first kibbutz was founded at Deganya, Israel, in 1910, primarily by Russian immigrants. There are fewer than 300 kibbutzim, with most formed prior to Israeli statehood in 1948. Kibbutzim range in size from about 40 members to over 1,000; however, most have between 300 and 400 members. In total, the kibbutz population is approximately 130,000, about 2.5% of Israel's population. Although early kibbutz founders were largely secular, ideological supporters of socialism and Zionism, religious kibbutzim began to appear in the 1930s. Most kibbutzim belong to one of three major movements, each with a distinctive ideology, although these distinctions have become blurrier in recent decades. The United Kibbutz Movement, usually referred to by its Hebrew acronym TAKAM, comprises approximately 60% of the total kibbutz population. Kibbutz Artzi, which recently decided to merge with TAKAM, includes over 30% of the kibbutz membership. The third

major movement, Kibbutz Dati, is composed primarily of religious kibbutzim.

Currently, the kibbutz movement is confronting what some observers characterize as a demographic crisis. Younger generations are leaving the kibbutzim, and the average age of the population is increasing. This demographic shift has prompted several adaptations in kibbutz living; for example, many kibbutzim are relying increasingly on paid workers for factories, agricultural tasks, and tourism services. Others are intensifying efforts to expand work exchange efforts, bringing in volunteers from within Israel and abroad. Despite the initial ideological commitments of the early kibbutzim to collective and egalitarian production, almost two thirds of the kibbutzim workforce is now comprised of hired workers. An additional strategy taken up by some kibbutzim as a way of coping with recent demographic shifts is the rental of housing to nonkibbutz members. Some kibbutzim have even built neighborhoods specifically for nonmembers. These shifts have contributed to the blurring of the line between the kibbutz as a social and economic entity and the kibbutz as a geographical/ municipal unit.

Kibbutz members also have more opportunity now for individual choices in higher education, the arts and literature, vacation time, and so on than was the case in the early days of the movement. This is possible in part because of shifts in the distribution of resources within the kibbutzim, in which more money is allocated to personal budgets than had been the case previously. Additionally, many kibbutzim now allow free choice of workplace, resulting in increasing numbers of kibbutz members working away from the kibbutz. These economic changes have resulted in increased hierarchy within the kibbutz, which is also reflected in shifts from political systems of direct democracy to representative democracy. These shifts have contributed to increased income inequality both within and between kibbutzim.

Changes in kibbutz life are also occurring in gender relations and the organization of family life. Ideologically, women are equal participants in the labor force, with all jobs open to them. In practice, most women work in education, health care, and other service positions, although in the earlier days of the movement women worked in agriculture. In contrast to early kibbutz practices that were designed to relieve women from domestic chores, today more women are seeking release time from communal kibbutz responsibilities in order to spend more time

at home raising their children. Although meals still tend to be eaten communally rather than in individual homes, the nuclear family structure has grown increasingly prevalent in kibbutzim. In contrast to early collective kibbutz housing, which reflected the movement's ideological rejection of the "ownership" of children, private homes with children raised by their parents rather than in communal children's houses have grown increasingly common.

Various commentators have been ringing the death knell for the kibbutz movement almost since its inception; nevertheless, it has continued to survive. The major challenge facing the kibbutz movement today is how to maintain the ideals associated with its communitarian history while adapting to current demographic and economic challenges.

KING, DR. MARTIN LUTHER, JR. (1929–1968)

Dr. Martin Luther King, Jr. was born in Atlanta, Georgia, on January 15, 1929 in an area that, today, is a national historical site. His father was a minister and a prominent member of the community who served as a pastor at a nearby church. During King's early days as a child, his parents attempted to shield him from some of the racial segregation policies characteristic of the time; however, racism permeated the atmosphere of his environment. A segregated society was a way of life that was even legalized by the United States Supreme Court in the famous case of *Plessy v. Ferguson* (1896), which established the important segregationist doctrine of "separate but equal." Even after this doctrine was later repudiated by the

Supreme Court in the momentous case of *Brown v. Board of Education* (1954), there was much to work for in terms of social justice.

In some ways King was fortunate. He came from a prominent family and had the opportunity to receive a fine education. In 1948, he received his bachelor's degree in sociology from Morehouse College, a prominent African-American institution located in Atlanta. Later he received his PhD from Boston University. King married Coretta Scott, and together they had four children. Coretta Scott King was to follow in King's footsteps, also making important contributions to the civil rights movement.

One of King's most notable influences was Mahatma Gandhi, a great political leader who helped India gain independence from Great Britain. From Gandhi, King learned the value of use of passive resistance to influence society and obtain a very important goal. King decided to advocate for passive resistance and to use it in his attempt to bring about justice and racial equality in the U. S.

King first received national attention (as well as threats and indignities) as a result of his participatory leadership in the famous Montgomery Bus Boycott that began in 1955. History has described his efforts in the boycott as a major success foreshadowing future gains in the civil rights movement.

In April of 1963 King authored his famous "Letter From Birmingham Jail," an excellent description and explanation of his philosophy to bring about social change in the U. S. In August of 1963, King gave his famous "I Have a Dream" speech before thousands in Washington, DC, expressing his desire for a time when his children might be judged by the content of their character and not by the color of their skin. In 1964, King received the Nobel Peace Prize, heightening his growing prominence on the national and international level. King was a key participant in the famous Selma March that led to the passage of the Voting Rights Act of 1965. Later he brought his advocacy of civil rights and equal opportunity to Chicago where he attempted to improve the quality of life for African Americans. His assassination in 1968 shocked the nation, but reinforced recognition of his accomplishments. King is buried in Atlanta, Georgia, the home of his birth. His tombstone reads, "Free at last, free at last, thank God Almighty, I'm free at last."

King was not the only person to make substantial contributions to the civil rights movement in the U. S.; however, his legacies are enormous and important. King increased the political, economic, and social opportunities not only for African-Americans, but also for other minorities. He caused Americans and others to contemplate the effects of their behavior on the less fortunate in society. Finally, his efforts are a reminder that the price paid for equality is often going to be quite high; equal treatment is a public policy that does not come easily.

KINSHIP AND DESCENT

Kinship and *descent* are each notions that have been of particular preoccupation to social anthropologists, as much due to their importance as because of the difficulties they present. It is worthy to note their close link, stemming from a common social and biological character (only the former being necessary).

In particular, *kinship* refers to social relationships that usually coincide with biological ones. This is the case with the two forms of *real kinship*: *consanguinity* and *affinity*. *Pseudokinship* or *fictitious kinship* takes place when the social relationships simulate the ones arising through real kinship (consanguinity or affinity) but without any biological relationship. For example, in many societies, children who are breast-fed by the same mother are considered siblings. We can view *ritual kinship* as a special form of fictitious kinship, which necessitates a ritual for its creation, rituals such as godparenthood, adoption, or fraternization.

The term *descent* denotes the relationship that bonds the child to its mother or father, through which the elements that constitute the main characteristics of their *status* are transmitted. These include name, surname, heritage, and so on. Descent rules determine mainly membership to the parents' kinship groups; in other words, descent is more of a social convention than a biological relationship. Consanguinity may exist, but it is in no way a necessary requirement. For instance, we consider adopted individuals (fictitious or ritual kinship) to have the same descent as the members of the group that adopted them. Just as it applies to individuals, descent can pertain to groups when group members biologically descend from a common ancestor or when they declare this to be the case, as slaves did by assuming membership of their owner's kinship group.

Morgan and especially Pitt-Rivers and Radcliffe-Brown formulated a series of theories that reproduction by way of descent is the main principle of kinship. These theories are known as *descent theories*. A different view to these older theories is aired by Lévi-Strauss's *alliance theory*, which links the exchange of women and the interdiction of incest as the organizational principles of kinship.

In all societies, kinship and descent are two different notions: Kinship is a social relationship that may or may not coincide with a biological one; descent is a social convention that may require a biological relationship.

Descent Systems

Descent systems determine the parents who transmit the main characteristics of individuals' status. Parents also determine our membership in kinship groups: our mother's, our father's, or both.

We can define descent as *bilateral* or *cognatic* when the characteristics of our status are transmitted through both parents and we belong to both parents' kinship groups. Most Western societies fall into this category, with children usually bearing their father's surname. We define descent as *unilineal* or *unilateral* when the elements of an individual's status are transmitted through only one parent and the individual belongs to only one parent's kinship group.

When the elements of an individual's status are transmitted through men, in particular the father, the descent is termed *patrilineal* or *agnatic*. In these cases, individuals belong to the groups constituted by their fathers' kin without overlooking their consanguinity links with their mothers. The Nuer in Sudan, as well as the ancient Romans, have kinship groups of typical patrilineal or agnatic descent.

Correspondingly, when the elements of status have been transmitted by women, by mothers in particular, the descent is called *matrilineal* or *uterine*. This descent was common among the Iroquois Native Americans, and it still happens in the Hopi tribe. In many matrilineal or uterine descent societies, the mother's brother has the primary role in the kinship group, corresponding to the father's role in cases of patrilineal or agnatic descent. In the Trobriands in Melanesia, the son belongs to his mother's kinship group in which her brother is also included; following the son's marriage, the son and his wife live with the said brother.

Some societies have an even more complicated descent system, combining matrilineal and patrilineal descent but with only one of them being commonly accepted. This system is termed *double descent* or *bilineal descent*, not to be confused with bilateral or cognatic descent, where descent is equally determined by both parents' sides.

In the Ashanti in Ghana, children inherit their fathers' "spirit" as a characteristic of their status, but they belong to their mothers' kinship groups, with whom they cohabit. A man and a woman who are distant patrilineal relatives are allowed to marry when it becomes impossible for them to name their common patrilineal ancestor, usually after four or five generations. Marriage is, however, strictly forbidden for all matrilineal relatives belonging to the mother's wider kinship group. Conversely, in the Yako in Nigeria, children belong to and live with the patrilineal kinship group. This patrilineal group is strictly exogamic; their matrilineal group is much less so. Here we have two unilineal descents juxtaposed.

Descent Groups

Extending our discussion of kinship and descent, a kinship group (either *lineage* or *clan*) may be of matrilineal, patrilineal, or double descent. *Lineage* is the wider group of individuals beyond the family who are interconnected through consanguineal kinship and who acknowledge a common ancestor. *Clan* is the even wider social group in which members acknowledge a common ancestry and whose relationships are ruled by solidarity. Whether the group is of matrilineal, patrilineal, or double descent depends on whether its members claim a common ancestor (who may be an existing or mythical person) and whether their characteristics are determined through the mother, the father, or both. These kinship groups are respectively known as *matrilineal*, *patrilineal*, or *double descent groups*.

The term *descent groups* is thus limited to unilineal or double descent groups. In the case of cognatic descent, there is no proper descent group, as neither patrilineal nor matrilineal relatives constitute a descent group because they both simultaneously belong to two kinship groups. Descent groups usually appear organized in such a way that enables them to make political, religious, or social decisions affecting their members. We call these *corporate descent groups*.

Descent and Residence

Because descent systems determine the kinship group to which individuals belong and with whom they usually cohabit, descent also appears related to the location of residence of both individuals and groups. When descent and locality appear parallel, that is, when patrilineal descent goes together with *patrilocality* or *virilocality* (residence with patrilineal relatives) and matrilineal descent goes together with *matrilocality* or *uxorilocality* (residence with matrilineal relatives), the descent system is described as *harmonic*. For instance, the patrilineal Nuer are patrilocal and the matrilineal Hopi, matrilocal.

There are cases, however, where descent and locality are opposed, as system we then describe as *disharmonic*. More specifically, a disharmonic system can combine either patrilineal descent with matrilocality or matrilineal descent with patrilocality. In Congo, for example, the husband lives in the same village as his father and sons (patrilocal residence) but belongs and inherits goods from his matrilineal descent group (matrilineal descent).

study in the social anthropology of kinship. Kinship terminology is a message carrier, concurrently reflecting and determining social behavior.

Kinship refers to social relationships that may or may not coincide with biological ones. The terms of kinship can, indeed, correspond to true kinship, with social relationships coinciding with the biological ones (*consanguinity* or *affinity*). When social relationships only simulate biological ones, the term we use is *pseudo-kinship* or *fictitious kinship*. The third type of kinship is a special form of fictitious kinship created through a ritual, such as godparenthood, adoption, or fraternization. The terms of pseudo-, fictitious, and ritual kinship are identical to the ones of real or true kinship.

Terms of Address and Terms of Reference

Independent of the category of kinship, we divide terms that describe related individuals into terms of address and terms of reference. Terms of address are the ones we use from birth (*Ego*) to address our kin, such as “Mum” or “Dad.” Terms of reference are the ones we use to refer to our kin in the third party: “my mother,” or “my father.” As these examples demonstrate, terms of address and terms of reference may be identical. Our use of kinship terms depends on how familiar we are with the relatives involved and the ages and genders of these relatives. Both terms of address and terms of reference exist only with respect to one another: “father” or “mother” implies there is a “son” or “daughter” and vice versa.

Classificatory Terms—Kinship Systems

Based on earlier work by both L. H. Morgan and G. P. Murdock, we now use six categories to classify systems of kinship: Eskimo, Hawaiian, Iroquois, Sudan, Crow, and Omaha. The main criterion for classifying a system is how the *Ego* uses the same term for different relatives. For instance, the kinship system of Western societies belongs to the Eskimo group, where the brothers of the parents are “uncles” and their sisters, “aunts.” In contrast, in societies belonging to the Hawaiian group of classification, the same people are “fathers” and “mothers,” respectively. Using the same term for different relatives entails a significant similarity in the behavior of *Ego* toward them, for example, the possibility of marriage.

KINSHIP TERMINOLOGY

The *terminology of kinship*, that is, the terms we use to name our kin, is one of the most important areas of

Descriptive Terms

Descriptive terms number but a few: father, mother, son, daughter, brother, sister, husband, wife. To eliminate any chance of confusion, we use each of these terms or a combination to describe only one relative. In the kinship systems of Western societies, individuals use descriptive terms wherever specific terms for each and every relative do not exist. For example, uncles from both the father's and the mother's side are not distinguished from the other; both are uncles. We can make the distinction because of descriptive terminology: father's brother and mother's brother.

In the Dinka and the Shilluk in Sudan, a special term-phrase exists for the relatives that Western societies call uncles and aunts: *brother/sister of mother/father*. Sudanese call every cousin *daughter/son of brother/sister of mother/father*.

Abbreviated Terms

Anthropologists invented abbreviated terms for methodological reasons, namely, simplicity and clarity. In both French and English, where fundamental terms of kinship are morphologically unlike each other, we can achieve what anthropologists envisioned. In English, the abbreviations of the terms of kinship consist of the first letter (or sometimes the first two letters) of the terms:

B: Brother

F: Father

M: Mother

So: Son

D: Daughter

H: Husband

Si: Sister

W: Wife

The abbreviated terms of kinship allow us to refer to relatives in ways that would be impossible using the particular terms of kinship in each society. For example, the abbreviation "MBD" refers to an individual's mother's brother's daughter, what the Ego would call "sister" in the Hawaiian system.

Fictitious, Ritual, and Pseudo-Kinship Terminology

We may use terms of real kinship in social relationships that result from fictitious or ritual kinship. For instance, children who have been breastfed by the same mother are *siblings* in many societies, but there is usually a more exact definition of this relationship: *foster siblings*. We may also use similar terms, such as *godfather-father* in English or *vëllam-vëlla* (blood brother-brother) in the archaic dialect of Albania called Arvanitika.

We may use terms of kinship metaphorically in cases where neither real, fictitious, nor ritual kinship is in place. For example, the inhabitants of the villages Didima, Karakassi, and Loukaïti (in Peloponnesus, Greece) address each other as *cousin*, referencing their reminiscence of a common ancestry, even when that relationship is distant.

Throughout Greece, the same term is used as a sign of familiarity between nonrelatives in a manner similar to the use of "friend" in English. The term *κονμπάροζ* (pronounced *koubáros*) that denotes the person necessary to accomplish a marriage, as well as the godfather, is used much in the same way. As a sign of respect, younger people and especially children may address adults as *uncle* or *aunt* and address the elderly as *grandfather* or *grandmother*.

Monks and other believers in the Christian church address each other as *brothers* and *sisters*, a practice with roots in the belief that all Christians are children of a "parental" God. Members of various organized groups, including religious groups or guilds, have also adopted terms of kinship and may call themselves *brotherhoods*. Examples of these are the *Confréries* in France and Belgium, whose name comes from *con* + *frère*, which translates as *jointly* + *brother*, such as the *Confrérie des Brasseurs* as a brotherhood for the brewers.

Whenever we require mutual support, we might use terms of kinship. For instance, we might call a more experienced co-worker who guides and instructs a newcomer in the workplace a *godfather* or *godmother*. Likewise, student *families*, such as those found in the colleges of the University of Cambridge in the United Kingdom, are composed of freshmen *children* and their co-student *parents*, more senior students who assume a guiding role.

KLUCKHOHN, CLYDE K. M. (1905–1960)

Clyde Kay Maben Kluckhohn was an early American anthropologist who made significant contributions to all four of anthropology's subdisciplines. One of the last true generalists in the field, Kluckhohn communicated his ethnographic research in the American southwest, as well as his theories on culture and society, to the public in accessible volumes such as *Mirror for Man* (1949).

Kluckhohn was born in Iowa in 1905. After completing his undergraduate degree in classics at the University of Wisconsin, Kluckhohn studied abroad, first at the University of Vienna in 1931, and then at Oxford University as a Rhodes Scholar in 1932. He completed his PhD at Harvard University in 1936 and was appointed to the faculty soon after; he spent his entire academic career at Harvard, where he taught anthropology and organized several interdisciplinary programs. Kluckhohn died in 1960 from heart failure while at work in New Mexico.

Kluckhohn's ethnographic contributions extend from his research in the American southwest. He gained firsthand experience with the Navaho when, at age 17, he was sent to New Mexico to recover from an attack of rheumatic fever. Kluckhohn published widely on Navaho society, most notably *Navaho Witchcraft* (1944) and *The Navaho* (1946).

Kluckhohn brought his eclectic knowledge of biology, psychology, and history to bear on his other major contribution to the discipline: the idea of culture. As a scholar, Kluckhohn was dedicated to moving anthropology away from the cultural relativism of Franz Boas and toward the search for human universals, a move he believed would gain anthropology a

place in the theoretical sciences. He pursued the search for universals in value theory, asserting that despite wide differences in customs, fundamental human values were shared across different societies. Kluckhohn communicated these ideas in works such as *Culture: A Critical Review of Concepts and Definitions* (with A. Kroeber, 1952).

Kluckhohn's interests ranged beyond the field of anthropology to include university administration and government service. At Harvard, Kluckhohn was Curator of Southwestern Ethnology at the Peabody Museum and a senior founding member of the Department of Social Relations. During World War II, he served as consultant for the Office of War Information where social science principals were used to analyze Japanese society. His early government service led to his appointment as the first director of the Russian Research Center. A product of the growing tension between the United States and the Soviet Union, the Center was dedicated to the investigation of Soviet society through the social sciences.

Koba, located in the northeastern Yucatán peninsula in the modern Mexican state of Quintana Roo, functioned as a Classic Maya metropolis. The center was also occupied in the Preclassic and Postclassic periods. The site includes prominent archaeological features such as pyramids, tombs, vaulted structures on elevated platforms, staircases, altar stones, stone carved slabs (*stelae*), and a complex set of roads (*sacbeob*) that connect the core area to the peripheries of the site and distant centers such as Ixil (20 kilometers to the

southwest) and to Yaxuna (100 kilometer to the west). The core of the 63-square-kilometer site includes a 1.5-kilometer-square area built on an artificial elevated platform which was the focus of the royal court, with large pyramid structures, elite residences, reception areas, broad stairways, and alley-like passageways. Koba was dramatically successful in creating an expansive Classic Maya regional center with its spoke-like *sacbe* system binding peripheral noble houses to the core area and serving as the boundaries of the contiguous suburban zones. Longer roads, trading expeditions, and warfare defined the limits of this regional state. The population of Classic Koba, estimated as 55,000, resided adjacent to the civic-ceremonial core and included greater nobles, lesser nobles, attendants to these, artisans, and modest commoners.

The Iglesia pyramid and the Nohoch Mul (Ixmoja) pyramid, located in the core area, are surrounded by vaulted architecture on both high and low platforms. The vaulted structures range from lavishly complex, double-wide vaulted structures to smaller, single-vaulted rooms. The functions of the central court area and its associated architectural forms are revealed through ethnography, ethnohistory, art history, and epigraphy. At Koba, this sector of the site is difficult but not impossible to interpret. The glyphic record at Koba is sadly eroded, the stone slab *stelae* inscriptions faded and in some cases broken; however, the ethnohistoric record provides some insight into the political importance of Koba. In addition, the ethnographic record of the Yucatec Maya lends some support to interpretation of the suburban zones, family structure, economic and political organization, and the religious symbolism and practice at the site.

One of the *stelae* at Koba illustrates connections between Koba and a woman from Naranjo, a Maya center located to the south. Through the tie to Naranjo, Koba was also bound to Tikal, but alienated from Calakmul and Caracol. Additional *stelae* at Koba mark the fortune and struggles of the center as part of the pre-Columbian Maya region.

Architecture and Construction

The central core zone and palace space at Koba is not like any other site: it is unique in its setting on the shore of Lake Koba and Lake Macanxoc, extending north to the Nohoch Mul group. Features include two ball courts, high platforms topped with double-vaulted

structures, altars, *stelae*, enclosed private courtyards surrounded by substantial constructions with vaults, staircases, and tombs. Multiple entrances into restricted courtyards are seen in buildings adjacent to the Iglesia pyramid, at the south and terminal end of Sacbe 27, and in the large, but perhaps unfinished, enormous mound to the west of the Nohoch Mul pyramid. Small spaces open onto large plaza areas (such as the zone in front of the Iglesia pyramid, from adjacent plazuelas, and from the high mounds and vaulted structures in the Coba Group B). Another large plaza area is found in front of the Nohoch Mul pyramid and main staircase. Large courtyards and the open plaza areas were the location of public theater, ritual and secular activities. More intimate enclosures (such as the modest plazuela behind the Macanxoc group, perhaps the area around the Las Pinturas group, smaller courts such as those associated with vaulted structures found at the end of Sacbe 27, and plazuela groups dispersed throughout the suburban zones) also functioned as loci for ritual celebrations and secular activities. Elite constructions involved high-energy investments in collecting the stone, rubble fill (*chich*), and plaster for stuccoing the walls. The amount of stone collected and shaped to construct the pyramids and some of the complex elite residential structures was enormous. Small *sascaberas* (granular limestone mines) for collecting raw materials for stucco are found adjacent to the perimeter of the central core area, in the northern survey zone, and elsewhere. In the suburban zones, platforms, vaulted constructions, and the foundations of pole-and-thatch housing required the collection of stone. Granular limestone for stucco, support beams, wall poles, and roofing thatch were required for construction of vaulted and unvaulted structures that served as shrines, residences, kitchens, storage buildings, and foundation stones for small garden areas. While stucco murals and fragmentary stucco in walls can be seen in the core area, stucco was also applied to walls outside the central zone. To the south, stucco walls were found at Dzib Mul and fragments of stucco can be seen on the high vertical walls on the east side of the Kitamna mound.

Administration and Court Structure

Classic Koba also housed principal and secondary nobles who performed key administrative duties and whose residences were located adjacent to the core in

residential zones and at the ends of the many *sacbeob* (roads) for which Koba is deservedly famous. Important positions associated with the ruler include his Baah Ahaw (“Head Lord”), the Sajal and Ah K’uhuum, Yahaw K’ak, (the “Fire Lord”), Yahaw Te (“Tree Lord”), Ebet (“Messenger”), Ah Baak (“Captive Taber”), or Baah Pakal (“Head Shield”). These and their associates managed the operations of Classic Koba, inside and beyond the city limits.

The rulers pictured on *stelae* at Koba had female counterparts. Costumes worn by royalty are only visible in carved stone *stelae*, but these carvings show elaborate feathered headdresses, and details of dress, as well as scepters of power characteristic of Maya kings and queens elsewhere. It is highly probable that the elite men and women at Koba wielded both supernatural and earthly power as they did elsewhere in the Maya zone.

Ceramic art of the period indicates the presence of powerful women: royal wives who forged powerful alliances between Maya kingdoms. The significant relationship between rulers and powerful women is also manifest at Koba where a royal woman from Naranjo is portrayed on a *stela* at the second ball court constructed near the Nohoch Mul complex. The rulers and the queens were accorded elite burials; although to date no noble woman’s tomb has yet been located, these high-status individuals would have carried symbolic codes in their dress, posture, and actions. The prime identifier for maize deities is the net overskirt of linked jade beads; both kings and queens are known to wear this garment, including the Koba queen from Naranja.

Documentation and Symbolism

The murals, glyphs and carved *stelae* found at Koba are badly eroded and faded but some records can be recovered. The *stelae* reflect important individuals involved in sacred and secular activities of import to the success of Koba as a central place. The decorated and elaborate figures mark dynastic histories, war triumphs and ritual common to Koba and other Maya centers.

Life at the Maya court is reflected in rulers standing on the backs of captives; seated on elevated platforms with cushions, pillows, and mats; in curtained rooms; in public spaces; dressed with care in elaborate costumes and headdresses. The *stelae* provide documentation of clothing; sandals; elaborate, feathered

headdresses; jewelry (jade, shell, and bone); elevated platforms for positioning rulers; associated attendants to the court (small dwarf figures representing companions to the Ruler/Maize God, manifestations of the dwarf/stubby malformed maize ears that commonly form on the corn stalk); and symbolism that reflects maize, cacao, and the calabash tree. The ceramics at Koba date primarily to the Late Classic Period (600–800 AD), although the site was occupied in earlier and later periods. The Late Classic pottery is Tepeu I and Tepeu II styles, and fragmentary.

The *quincunx*, symbol of the Maya four directions and the center, appears as a decoration on the stairway to the north of the Iglesia patio and marks the entrance to the first ball court reconstructed at Koba. The staircase may have been designed to celebrate victory and bring the battle to the Maya court as ballplayers marched down the stairs into the playing field. Battles were played out on the ball courts that merge secular and sacred space. Who the Koba warriors were fighting and why remains unclear, but elaborate trade relations and tribute payments may have been cemented through military subjugation.

Maya warfare focused on the capture of enemies, and these conquests were incised on Koba *stelae* where captives, with their wrists and feet bound, are crouched beneath the feet of rulers.

Maize, Myth, and Sacrifice

The Classic Maya gave central importance to the life cycle of maize, including attention to the wet and dry seasons; crop planting; and its sprouting, ripening and harvesting, as well as activities associated with processing the kernels (removing them from the cob, grinding them, and the nixtamalization process). The tragic adventures of the Maize God in the Underworld, his death, and resurrection, and the adventures of the Twin Heros (Hunahpu and Xbalanque) represent a story of epic proportion retold in the Popol Vuh. This epic has deep roots that reach back into the Classic and perhaps Preclassic Maya Periods: A Maya lord seated on top of a mountain or stone was recognized as part of the story of the Maize God; the Maya ruler on an elevated platform was identified with the Maize God; the Maya lords living on top of high, elevated platforms in cavelike, vaulted, stone buildings impersonated the Maize God. The site of Koba is riddled with metates in the core area and in the suburban zones. Noble residences

with domestic structures and associated metates document significant processing of maize on the household level and in the central zone. In addition, Koba also has round altars that may have been used as sacrificial stones, with the victim's body recognized as the symbolic center for the sprouting of maize (as illustrated by Maya artists at Piedras Negras, Peten, Guatemala, in the Codex Dresden and Codex Tro-Cortesianus, and in the Temple of the Warriors and Temple of the Jaguars at Chichen Itza).

Offerings excavated at the La Iglesia pyramid beneath a reset *stela* revealed shell, cinnabar, jade, and pearls as symbolic reflections of the Maize God, blood, death, and resurrection. A second offering in front of the first included seashell, jade, shell beads, and unworked hematite, replicating the first offering and reinforcing the symbolic associations of maize, death and rebirth. A third offering associated with La Iglesia revealed a censer, a monochrome plate, and miniature mano and metate, also representing association with the Maize God and suggesting rituals performed by the ruler as the Maize God impersonator. A skeleton buried in La Iglesia, with jade beads in each hand, illustrates the Maize God interred in the Iglesia mountain underworld.

To the north of the pyramid structure, the first ball court reflects the struggles of the Maize God and his brother, as well as the activities of the Hero Twins in the Popol Vuh epic. The second ball court at Koba has a ceramic skull located in the center of the playing field. The courts represent "places of sacrifice" associated with elements (such as the calabash tree, jaguars, sacrificial knives, mosquitoes, coatimundi, squash, ants, vampire bats, blowguns, comal griddles, masa corn meal), as well as with cunning, wit, and transformation. The ball courts at Koba reflect Maya symbolism, sacrifice, and resurrection as is recorded in the Popol Vuh epic as well as

the importance of maize, other plants, and animals in the Maya world. While burials and offerings at Koba that include jade (acquired by long-distance trade) represent the Maize God's costume minimally in comparison to the royal jade masks found with kings interred at Palenque and Calakmul, the symbolism is present and clear.

One significant obsession of Maya royalty was the emulation of the life of the underworld deity known as God L, the wealthy god of trade and tobacco, whose palace was richly furnished with objects desired by Maya kings. God L, old and toothless, with jaguar attributes, exhibited richly brocaded capes and extravagant feathered hats; frequently, his attendant owl was perched on his head. Beautiful women attended to his needs, and he received the frothy chocolate, a beverage preferred by the Maya nobility. God L was associated with the Rabbit scribe and the Moon Goddess, and because of this he is of particular interest in a discussion on Koba. The La Iglesia group at Koba is a place associated with reverence to the Moon Goddess, Chibirias (or Ix Chebel Yax) in contemporary local mythology. The Moon Goddess is known to be associated with abundant rebirth and regeneration in maize mythology and,

according to Redfield and Villa Rojas, *campesinos* (farmers) in Chan Kom have reported that maize is grown following the lunar calendar. Local hunters continue to burn candles and incense before they enter the forest at night. The hunters seek deer, an animal associated with Blood Woman (mother of the Hero Twins). God L, the Rabbit scribe, the Moon Goddess, and the Maize God perform their parts in the Maya epic story, played out in ball courts and adjacent zones at Koba. God L, as trader (clearly manifested in the murals at the site of Cacaxtla), was tied not only to maize but also to cacao. These two crops, central to the Maya economy, can be seen on ceramic vessels documenting the connection between cacao and maize, as well as the economic and symbolic significance of these crops. While maize is known to have grown successfully in the relatively moist climate zone around Koba, it has been suggested that Ixil served as a “bread basket” zone to the southwest of Koba, connected by a substantial *sacbe* (roadway). The moister climate may also have allowed the growth of cacao at Koba (which was also grown to the south in Honduras). Deep cenotes around Koba could have served as microclimates for cacao cultivation; there is evidence that a large cacao tree was known to thrive in a cenote in the southern zone at Koba until a decade ago. The ability to grow even a few cacao trees in a cenote would have heightened the political and economic power of the Koba rulers. As documented on ceramic iconography; the Maize God is linked to the cacao tree. Cultivation of fruit, fiber, bark, and resin was important in the Maya garden city and reflected social organization.

Another possible transformation of the Maize God appears in the calabash tree. One Hunahpu (the father of the Hero Twins and representative of the Maize God), appears as a head in the calabash tree. Maize, cacao, and the calabash tree were all prominent features in the environs of Classic Koba; their high productivity would be associated with royal, economic, and political clout. The Koba ball courts and caches of jade, cinnabar, pearl, and shell document royal concerns for these trade and prestige products.

The Hero Twin Hunahpu loses his head to the gods of the Underworld, and may be represented by the skull in the second ball court at Koba. His skull is only a temporary loss, replaced by squash and then reattached; however, he later sacrifices himself with his twin brother by leaping into the fire. Their bones are

ground down to *masa* (corn powder), thrown into water, and reconstituted as fish, fish-men, and the Tricksters who defeat the Lords of the Underworld to emerge as the Sun, Moon, and Venus. The three celestial images were probably observed and plotted from the Cono or Xaibe observatory at Koba. The structure has been reconstructed; alignment with the adjacent pyramid/mountain, the Nohoch Mul, and other structures reflects the astronomical prowess of the Maya residing at Classic Koba.

Myth as Urban Organization

Koba, in line with findings and interpretations elsewhere in the Maya region, depicts the contrasts between agricultural wealth based on maize, and commercial wealth based on cacao. The *stelae*, murals, vaults on platforms, and pyramids attest to the complex nature of Maya urban organization at Koba, and to the struggles and strength of the social groups residing in the city and beyond. The clearest portrait of Maya social dynamics was played out in the ball court where king and queen, father and son, agriculture, trade, politics, and religion are patterned as epic myth and social realities.

Human remains have been excavated at Koba, including an adult interred in a filled chamber associated with the La Iglesia pyramid. A reburied skeleton of an adolescent has been excavated in a small stone crypt. Burials outside the core have not been located but single structure units may have served as barrio shrines, perhaps associated with burials, as noted elsewhere in the Maya zone. What made Koba able to rise to its social, political and economic heights, and what caused the center to falter and collapse? What allowed the nobles of Koba to connect to the southern Peten zone? What permitted the center to gain access to pearls, shell, cinnabar, jade, and obsidian among other exotic and valued goods? Who were the rulers that guided the city? Who were the warriors and traders that protected and provided the goods that enabled the city to thrive? An understanding of these issues is yet to be achieved; however, it is clear that the center rose to great heights and accomplished massive tasks in building pyramids, palaces, and vast numbers of house compounds (both large and complex, as well as modest and simple structures). One clue to the builders' intent might be the blue-green color seen on fragments of stucco and in faded murals at Koba; blue-green represents the fifth

direction, the center: the union of celestial, terrestrial, and underworld levels of the cosmos.

Beyond the stark realities of politics and economic life, the people of Koba clearly designed the center to merge secular, sacred, and mythic in a rich pattern that characterized Classic Maya culture and was to endure in contemporary Maya culture, albeit, in an innovative pattern.

KÖHLER, WOLFGANG (1887–1967)

Wolfgang Köhler was born on January 21, 1887, in Rivel, Estonia. He was educated at the Universities of Tübingen and Bonn, and at the University of Berlin where he received his PhD in 1909. His doctoral dissertation was on psychoacoustics. Köhler is best known for his research in comparative psychology on the intellectual and problem-solving abilities of

chimpanzees (*Pan troglodytes*), and for his involvement with Gestalt psychology.

From 1913–1920, Köhler was the director of the Anthropoid Research Station on Tenerife, Canary Islands. The research station was established by the Prussian Academy of Sciences to study the behavior of various primate species in hope of ascertaining where they fell along the evolutionary continuum, especially in comparison to humans. Köhler's observations and studies of the nine chimpanzees housed on Tenerife were summarized in *The Mentality of Apes* (1925).

Köhler recognized that chimpanzees are intelligent creatures, and that their behavior in natural settings resembles that of humans. On Tenerife, he observed chimpanzees interacting with one another during contrived problem-solving tasks. Some tasks involved using items such as sticks, boxes, and ropes to access food that was out of reach. The chimps attempted to obtain the food in various ways, using mostly trial-and-error methodology. Köhler noted that the chimpanzees appeared to survey the scene, think of a possible solution to the problem, and then act upon it. It seemed to Köhler that the chimpanzees suddenly came upon solutions, evidence for the chimpanzees doing the trial-and-error learning in their minds rather than outwardly, which Köhler believed was suggestive of insight learning.

Köhler and colleagues believed that the mind perceives things in the most organized and simplistic way possible. Along with fellow theorists such as Kurt Koffka and Max Wertheimer, Köhler believed that the whole of a system could be greater than the sum of its parts. With this theory, they created a new branch of psychology known as Gestalt psychology. Although Max Wertheimer is usually attributed with being the founder of Gestalt psychology, some people also credit Köhler; however, the theory itself dates back to Christian von Ehrenfels' *Über Gestaltqualitäten* (1890). The word *Gestalt* is of German origin and literally means pattern or organized whole.

After leaving Tenerife in 1920, Köhler became director of the Institute of Psychology at the University of Berlin. He was a visiting professor at Clark University (1925–1926), a William James lecturer at Harvard University (1934–1935), and a visiting professor at the University of Chicago (1935). By 1935, there was mounting pressure and social change from the Nazi regime that eventually affected the University of Berlin. Köhler publicly criticized Nazism, and

his clinic was raided twice by Nazi supporters; as a result, Köhler decided to accept a research professorship at Swarthmore College in Pennsylvania, where he stayed until 1958. Köhler remained an active researcher and lecturer for the remainder of his life. On June 11, 1976, at the age of 80, Köhler passed away at his home in Enfield, New Hampshire.

KOKO (LOWLAND GORILLA)

Koko is a 180-pound, lowland gorilla who has been taught American Sign Language by developmental psychologist Francine “Penny” Patterson since July, 1972. Born on the fourth of July, 1971 at the San Francisco Zoo, the gorilla was named Hanabi-ko (Japanese for “fireworks child”), but she is best known by her nickname, Koko. With the possible exception of King Kong, Koko is perhaps the world’s most famous Great Ape. She has appeared hundreds of times on national television and the covers of magazines such as *National Geographic*. As Koko is purported to have a vocabulary of more than a thousand signs, anthropologists and linguists have been intrigued by her apparent capacity for complex, human-like

language. Children and her other fans, however, are simply fascinated by her charm: Koko loves to look at pictures in books and magazines; she paints, and she has raised several kittens.

While not every researcher agrees with Penny Patterson that “she’s just as much a person as we are,” Koko is an ambassador and “spokesperson” for wildlife conservation, endangered species, and refuge projects for primates. Koko’s Gorilla Foundation—with its website, newsletters, and other promotions—have kept ape-language research in the public consciousness, even though it has lost much of its earlier momentum in the scholarly community. While Koko’s website says she wants to have a baby and that she will teach her child to talk, her past romantic encounters (such as with her first boyfriend, of sorts, Michael) have not been encouraging. As Koko progresses through her mid-30s (which is long-lived for gorillas in the wild), the possibility of pregnancy is decreasing yearly.

In the 1970s, interest in communicating with primates using sign language, computers, or other artificial devices not only captured the public’s imagination to be able to “talk to the animals,” but also seemed to be a very promising line of scholarly research. Psychologists, biological anthropologists, and those who studied language acquisition believed that these ape sign-language experiments could offer much insight into human evolutionary cognitive and linguistic development. Of all the apes studied, Koko appeared to be the most facile, and even some introductory anthropology textbooks were saying that she knew some 2,000 English words. If this were true, it would put Koko on par linguistically with a 5- or 6-year-old human child.

Patterson now gives a more modest figure for Koko’s accomplishments: a working vocabulary of 500 signs with approximately another 500 signs she has said herself on one or more occasions. Yet, more important than the mere number of different vocabulary items attributed to Koko are the quality and kinds of language she uses. For example, one of the characteristics that is often said to separate human from nonhuman language is productivity: the ability to coin new words for new phenomena. Koko apparently does this quite often, such as making the sign combination *eye hat* for “mask,” *elephant baby* for a Pinocchio doll, or *white tiger* for a toy zebra. While other primates have used signs productively (such as the chimpanzee Washoe’s famous *water bird* for

“duck”) Koko’s neologisms seem more abstract, as the component parts of her new signs are not actually physically present when she creates them. She also has a very colorful and creative vernacular vocabulary of expletives. When Penny playfully put a salt shaker on her head, Koko called her *head stupid*. When asked what she thinks of her gorilla friend Michael, she has replied, depending on her mood, *think stupid devil*, *rotten devil*, or *toilet*.

Another characteristic of human language is that of displacement: the ability to talk about something beyond the immediate present or geographic locale. Below is an often-quoted discussion with Koko about death. Koko was asked to pick out the gorilla skeleton among four types of animal skeletons. After she picked the gorilla skeleton, the trainer asked her if this was an alive or dead gorilla. (It should be noted that the sign for *drapes* is polysemous for Koko, referring to security, providing security, or being afraid.) Her answer:

Koko: *dead drapes*

Trainer: Let’s make sure, is this gorilla alive or dead?

Koko: *dead good bye*

Trainer: How do gorillas feel when they die—happy, sad, afraid?

Koko: *asleep*

Trainer: Where do gorillas go when they die?

Koko: *comfortable hole sleep*

Trainer: When do gorillas die?

Koko: *trouble old*

By the 1980s, enthusiasm for the ape-language had drastically waned. This was partly due to dismissals by theoretical autonomous linguists of the Chomsky school (e.g., Joel Wallman, Lyle Jenkins) and many cognitive scientists (e.g., Steven Pinker). Also, increasing funding for AIDS research caused a chimpanzee shortage at animal laboratories, and some universities and primate centers found they could no longer afford to operate as their funds were cut or transferred to medical research. Patterson left Stanford University and established the private nonprofit

Gorilla Foundation whose primary purpose was to continue the language project, increase public awareness of gorillas as a threatened species, and provide a home for Koko.

Some of the criticisms leveled against all ape-language experiments can be seen in the following excerpt from a national AOL Live Internet Chat held in 1998 between Koko and Penny Patterson at the Gorilla Foundation, and a moderator and various questioners:

Moderator: Welcome Dr. Patterson and Koko, we’re so happy you’re here.

Patterson: You’re welcome.

Moderator: Is Koko aware that she is chatting with thousands of people now?

Koko: *good here*

Patterson: Koko is aware.

Questioner 1: Koko, are you going to have a baby in the future?

Koko: *listen Koko loves eat*

Moderator: Me too.

Patterson: What about a baby? She’s thinking. . .

Koko: *unattention*

Patterson: She’s covered her face with her hands. . .which means it’s not happening, basically, or it hasn’t happened yet.

Koko: *I don’t see it.*

Moderator: That’s sad.

Here we see prompting by Patterson when Koko is silent, an interpretation provided when Koko’s response is inappropriate, and a filling in of details not actually spoken by Koko.

Patterson has made surprising claims about Koko, even claiming that she has an IQ of 80.3 on standardized human intelligence tests. Perhaps because of their popularity in the mass media, Patterson and Koko are more harshly criticized than other ape-language researchers.

But these critics are perhaps being narrow minded. One reason Patterson and Koko's conversations are so interpretive may be due to the fact that they have never been apart since their language research started. As the science writer Eugene Linden noted, "Their relationship has all the overlays of love, bickering, and resentment. . .between a mother and a daughter who have spent their lives closeted together. . . . Were Koko human, their life together might have been a fitting subject for treatment by Tennessee Williams. Koko and Penny know each other so well that merely to read a transcript of their signing conversations is to glimpse only a very small portion of the interplay between them."

KOVALEVSKII, ALEKSANDR O. (1840–1901)

Russian biologist Aleksandr Kovalevskii (Kowalevsky) is notable for his foundational contributions to modern comparative embryology. Raised in a secular society with his brother Vladimir, Kovalevskii received his master's degree from St. Petersburg

University for his studies of *Amphioxus lanceolatus*. The results from his research gained him admittance into the Russian Academy of Sciences, the Paris Academy of Sciences, and the Royal Society of London. Although Kovalevskii had won acclaim and prestige for his research, civil and academic political restraints prevented him from teaching at the leading academic centers of St. Petersburg and Moscow. Resigned to less-equipped provincial universities, he spent the rest of his academic career in Kazan, Kiev, and Odessa. In honor of Kovalevskii's achievements, the St. Petersburg Society of Naturalists created an international award, The Kovalevskii Medal, for advancing accomplishments in comparative embryology and zoology within an evolutionary framework. Applied to the study of phylogenetic relationships, Kovalevskii's contributions are foundational to Russian Darwinism.

Contributions and Perspectives

Influenced by Charles Darwin's theory of organic evolution, Kovalevskii's research into evolutionary embryology yielded insights into the relationships among species within a taxonomical framework. In his inquiry into the vertebrate *Amphioxus lanceolatus*, Kovalevskii suggested that this species could represent a transitional phase between vertebrates and invertebrates. Upon his initial research, he found that the embryonic development depicted two distinct developmental phases; the first phase resembles invertebrates, and the second phase resembles vertebrates. During this process, appearance of both egg and blastula is later followed by an embryo with both internal and external germ layer found in vertebrates. It was shown that within embryonic development, both vertebrates and invertebrates are similar; consequently, this discovery resulted in the reclassification of the lancet from vertebrate to invertebrate. Furthermore, Kovalevskii's inquiry into ascidians provided evidence that the developmental growth of these sea organisms closely parallels vertebrate development. Inquiry into embryonic development of other invertebrates exhibits similar development. Similar to Darwin's experiences that led to his discovery of organic evolution, Kovalevskii's study of marine life led to the finding of related species among the waters of both the Red and Mediterranean Seas. His findings provided further support for Darwin's scientific determination and opinion regarding embryonic development as possible terms in taxonomical evaluations.

Although Darwin's theory of organic evolution was not without its critics in Russia, most notably Karl von Baer (1792–1876), the mainstream of anti-Darwinian thought consisted of objections to transitional forms of species. Insufficient comprehension of heredity (genes and mutations) and the nature of adaptation allowed for the resurging fundamental principles of Aristotle (348–322 BCE) and Carol Linnaeus (1707–1778). Steeped in teleology and a designed ontology, the ensuing political climate (academic and social) differed slightly from today. In spite of this climate, Kovalevskii contributed evidence to the validity of Darwin's theory of evolution with the mechanism of natural selection within the biological sphere of marine life. Kovalevskii corresponded with Darwin, informing Darwin as to advancements in his own research and assisting with the translation of Darwin's publications that influenced embryology in both Russia and Western Europe.

KOVALEVSKII, VLADIMIR O. (1842–1883)

Russian paleontologist Vladimir O. Kovalevskii was noted for his contribution to the development of phylogenetic sequences or stages of evolution in species with an adaptive perspective. Brother to biologist Aleksandr, Vladimir is perhaps best known for his depiction of the transitional sequence involving the species *Equus*. Although educated in law as an undergraduate, he paid a heavy price for the transition to paleontology, first failing his examination at Odessa University and then failing to find suitable employment. Encountering opposition at every level, Vladimir was eventually appointed to Moscow University, a career cut short by his suicide in 1883.

Contributions and Perspectives

Influenced by the works and personal correspondence of Charles Darwin, Vladimir disseminated evolutionary theory by translating Darwin's works and supported his own research by publishing several monographs (one of which, *Anthracotherium*, he dedicated to Darwin). In addition, by translating other significant scientific and philosophical works, for example, Charles Lyell's *Antiquity of Man*, Kovalevskii typified and implemented the historical approach to the evolutionary perspective. This perspective was critical for the development of paleontology within Russian academia, through which Kovalevskii stressed the importance of fossils, biology, and ecology of species within an evolutionary and historical framework.

Kovalevskii's greatest contribution was reconstructing the evolution of the common horse, *Equus*. Using what we consider functional morphology, he studied the range of hooves or ungulates and arranged them into morphological variants (adaptations) and geological time. When viewed in this perspective, the lineage depicted several morphological changes: increase in size, modification of digits, and differences in dentition or the character of the teeth. When we interpret these changes through historical and geological time, it becomes apparent that the physical adaptations were a result of a changing ecology, thus supporting the Darwinian idea of natural selection.

Kovalevskii's research supported Darwin's theory of organic evolution and the mechanism of natural selection, implemented an active approach to phylogenetic reconstruction, and established a comprehensive view of what would later develop into anthropology. Fighting against the political and academic restraints of the time, the very restraints that would contribute to his death, Kovalevskii tied Russian thought and science to Western Europe. This affiliation with the West and Kovalevskii's overall contribution to scientific thought advanced unity in Russians' view of life. Kovalevskii had provided the physical evidence to support not only his own personal perspective but also to reaffirm the materialistic interpretation of Darwinian evolution.

KROEBER, ALFRED LOUIS
 (1876–1960)

Alfred Lewis Kroeber was an early American anthropologist who made significant contributions to all four of anthropology's subdisciplines. Kroeber is significant for his research on North American indigenous populations, his dedication to characterization and classification methods in ethnographic research, and his advancement of a definition of culture as a superorganic phenomenon. He established one of the most important centers for anthropological research at the University of California, Berkeley, where he trained a generation of anthropologists such as Julian Steward and W. D. Strong.

Kroeber was born in New Jersey in 1876 and grew up in New York City. He earned his bachelor's (1896) and master's (1897) degrees in English; Kroeber eventually obtained his doctorate (1901) in anthropology at Columbia University under Franz Boas, the founder of American anthropology. Kroeber moved to California in 1900 where he spent the bulk of his life, first as curator at the California Academy of Sciences, and later as a founding member of Berkeley's Department of Anthropology. After a lifetime of research and teaching, Kroeber died of heart failure in 1960 while on holiday in Paris.

Kroeber asserted throughout his career that all societies were historically unique and should be observed holistically to appreciate all constituent aspects (e.g. kinship, religion, language). As a result, Kroeber developed methods to characterize and classify the cultural traits of a society. One such example included recording the elemental distribution of cultural traits across North America in order to trace their evolution and write the culture history of indigenous populations. This work greatly informed Kroeber's observation of culture as superorganic, a

phenomenon that develops according to internal laws and is immune to human intervention. The idea of culture as a superorganic phenomenon dominated anthropology in the following decades.

Kroeber's contributions to anthropology's subfields of linguistics and archaeology were remarkable. Understanding language to be the ultimate cultural trait, he recorded several disappearing languages during his fieldwork among California's indigenous populations. In his work on kinship terms, Kroeber developed what would later be termed *componential analysis*, in which language, when broken down into constituent components, could be categorized according to designated criteria. Kroeber was drawn to archaeology due not only to his curatorial responsibilities, but also in his quest to reconstruct American Indian culture histories. In his excavation and research in the American Southwest, the Valley of Mexico, and Peru, Kroeber was most concerned with ceramic styles and sequences. As a result, he introduced seriation into archaeological research, by which material culture is arranged in the order that produces the most consistent patterning of their cultural traits.

**ALFRED LOUIS KROEBER**

Cultural anthropologist Alfred Kroeber is best known for his work with indigenous peoples of North and South America. Following in the steps of his teacher and mentor Franz Boas (1858–1942), Kroeber and anthropologist Roland B. Dixon (1875–1934) devised new classifications for American Indian languages. While at the University

of California, Berkeley, Kroeber also became involved with examining the Peruvian pottery collection excavated by Max Uhle (1856–1964). In 1926, Kroeber and Donald Collier traveled to Nazca on the south central coast of Peru to excavate cemetery sites in order to learn more about pottery styles of ancient civilizations.

Kroeber's 1928 account of the expedition has become a classic work in anthropology, arousing interest in Peruvian archaeology and influencing the work of generations of anthropologists. Edited by Patrick H. Carmichael, Kroeber's *The Archaeology and Pottery of Nazca, Peru* was reprinted in 1998, further demonstrating that Kroeber's detailed documentation has continued to set high standards for the rapidly expanding field of Peruvian anthropology.

On the basis of new radiocarbon dating methods, archaeologists in Peru announced in 2001 that the site of Caral is now believed to be the oldest city located in the Americas. Caral, which is located some 125 miles north of Lima, is now thought to date to 4,090 years ago. Under the leadership of Winifred Creamer of Northern Illinois University and Jonathan Haas of the Chicago Field Museum, archaeologists uncovered a vast complex of ceremonial and administrative buildings.

Caral is one of the largest cities located in the Supe Valley, where a number of other ancient sites have also been discovered since excavations began in 1941. The Supe Valley extends some 90 kilometers from the Pacific coast to the Andes Mountains. Examination of the Caral site has revealed that its residents lived on vegetables and seafood rather than on various grains as was more common at the time. Evidence of irrigated farming has also survived. Archaeologists have identified sophisticated architecture that includes low platforms, hearths, terraces, enclosures, and a sunken, circular plaza. Archaeologists who examined a present-day canal believe that a prehistoric canal existed in the same location.

New discoveries continue in Peru; in February 2005, archaeologists announced the discovery of some 50 etched figures found on the hills of the south coastal area of Palpa that likely predate the earlier discovery at Nazca of similar figures.

According to Johnny Islas of the Andean Institute of Archaeological Studies, the figures at Palpa (depicting human beings, birds, monkeys, and felines) are assumed to have been created by the Paracas between 500 and 100 B.C.E.

KROPOTKIN, PRINCE PETER A. (1842–1921)

Peter (Pytor) Alekeyevich Kropotkin was a revolutionary and a philosopher; he was known for his works in other fields such as zoology, anthropology, and sociology. Kropotkin was the son of Prince Aleksey Petrovich Kropotkin of the old Russian aristocracy. He was educated in the elite Corps of the Pages, a special military school for boys of noble birth. From 1862 to 1867, Kropotkin served in the Army as an officer in Siberia; while there, he carried out original studies on cartography and geomorphology. Kropotkin proved that eastern Siberia was acted upon by post-Pliocene, continental glaciations. He found similar evidence in Finland and Sweden, thus theorizing that glaciers had once covered the northern plains of Eurasia and North America. A prolific writer, he developed his theories of libertarian communism on the principle of mutual aid, while observing tribal communities and the social life of the wild animals in Siberia.

As a result of his studies of animal life, Kropotkin theorized that mutual aid was the key to understanding human evolution. Most animals live in societies; Kropotkin believed that the survival strategy of safety was a concept needing closer examination, not just as a struggle for existence, but as protection from all natural conditions any species may face. Each individual increases its chances for survival by being a member of a group. Mutual protection allows certain individuals to attain old age and experience. With humans, collective groups allowed for the evolution of culture.

In the earliest band societies, social institutions were highly developed. In the later evolution of clans and tribes, these institutions were expanded to include larger groups. Chiefdoms and state societies

carried this mutual identity to groups so large that an individual did not know all members. The idea of common defense of a territory and the shared character of nationalism appears in the growth of the group sharing a collective distinctiveness.

Kropotkin believed that science and morality needed to be united in the revolutionary project; education ought be global, humanistic, and empower everyone equally, and children should learn not only in the classroom, but also in nature and in living communities.

Mutual aid remains a necessary part of the life of any family, band, city, or nation. It becomes even more important for smaller groups in surviving the rule of an elite. Mutual aid becomes the foundation for our ethical systems; ethics is the basis of our biological evolution, and in this morality lies our collective material existence in nature. Kropotkin claims anarchism would extend mutual aid from family to include all of humanity. This idea of *universal ethics* is the origin of all universal religions and philosophies.

Kropotkin's economic analysis began not with production, but with consumption established upon human needs. Needs are the starting point of production decisions; needs should not be determined by the greed and avarice of the individual. Economies should guarantee that all peoples' needs are met with the least waste of energy. Hunger and want is the fault of an improper economic system, and not the fault of nature. Only an economy of mutual aid can meet all peoples' needs; these needs include not only biological needs, but also all creative and emotional needs to live for the purpose of living the most meaningful life possible. Artistic creativity and concern for the well-being of oneself and others is the foundation for social morality, artistic creation, and the will to work at jobs that benefit the community.

According to Kropotkin's theory, each community would produce as much of its local needs as possible, exchanging only what it can produce in surplus for what it cannot produce. Mutual aid and voluntary cooperation eliminate the need to motivate labor through greed, hunger, or coercion. Kropotkin stated that even those who do not work should be fed, as they are but the "ghosts of bourgeois society." He felt strongly that most people would contribute to the well-being of others as long as they freely chose to do so.

Kropotkin believed that people easily can have all they need to be truly happy and healthy, and to live a

meaningful life. In labor, work and art must be united. Through the rotation of jobs, all people share in both the noxious and creative work. Joy and responsibility cannot be separated. The separation of mental and physical labor can be eliminated. Decentralization can help reduce the poverty of separation of humans from nature.

Kropotkin believed it is possible for people to create a society in which unbridled wealth as well as all poverty can be eliminated. With wages or property, people could live in luxury with every need being met. This society can be achieved, Kropotkin wrote, only through propaganda of the deed, and through direct action. This unites a collective insurrection with a collective construction of society.

A large portion of contemporary social and biological science follows in the footsteps of Kropotkin's academic work. Responding to the social Darwinism of his day, he wrote his primary scientific work, *Mutual Aid: A Factor of Evolution*, arguing that a major factor in the evolutionary success of humans

was a predisposition to cooperate and share without the need for institutions such as the market or the state.

Research in anthropology has provided substantial confirmation to supporting mutual aid in non-market economies. Karl Polanyi, among others, has shown that a moral economy can and does exist. Anthropologists continually show extensive decentralized cooperation based upon reciprocity and redistribution. Marshal Sahlins writes that, in many cultures, selfishness is not rewarded. Substantivist economists have shown that people often give away substantial amounts of wealth. In many cultures, people actively cooperate against their own narrow self-interest. This is not simply “enlightened self-interest,” it is a genuine need for justice as its own justification. Biologists have acknowledged that competition among early human groups could have contributed to the evolution of cooperative behavior on the part of individuals. Both cooperation and competition has existed in the past.

In 1871, Kropotkin dedicated his life to social anarchism, mostly because of his observations of animal and human communities in Siberia during his military service. In 1874 he was imprisoned in Russia for his radical actions and beliefs. In 1876 he escaped and went into exile, fleeing first to Switzerland, then France, and finally settling in Britain in 1886. He supported the allies during World War I; because of this, he lost much of the respect he had held from his fellow anarchists. Because of the Russian Revolution, Kropotkin was allowed to return to Russia in June, 1917. Although Kropotkin was respected by both the Bolsheviks and the opposing forces, he was critical of both sides. After the Bolshevik Revolution succeeded in overthrowing the Revolutionary Provisional Government of Kerensky, Kropotkin strongly argued that a vanguard couldn’t make a revolution; only the people can fight a revolution and establish freedom. The Bolsheviks did not listen; brokenhearted, Kropotkin died in his beloved Russia in 1921.

For anthropologists, Kropotkin’s work on mutual aid is perhaps his most important contribution, not only in terms of his argument for the moral basis for communist anarchism, but also as the base for his theories of human evolution.

The term *Kula Ring* refers to the circulation of shell valuables between island communities in the Milne Bay Province of Papua New Guinea. Bronislaw Malinowski was the first anthropologist to document the exchange in a classic anthropological text, *Argonauts of the Western Pacific*, written in 1922. Anthropologists working in the latter half of the 20th century have clarified many of the local characteristics of the kula from different island perspectives.

Visualizing the exchange as operating within a ring is somewhat misleading, as not all island communities are involved, nor do all communities within islands participate in the exchange, although it could be argued that all people in the Milne Bay are affected to some extent by the exchange. The majority of shell valuables that circulate in the exchange are regularly diverted from the kula and put into other local exchanges to satisfy people’s more immediate exchange obligations. Entrepreneurial skills are needed for the kula man (and sometimes woman) to find a replacement and reenter it into the kula; otherwise he will lose all standing as a reliable kula partner, thus affecting his career in the kula. Unmet kula obligations may also threaten his life.

There are two shell ornaments circulated against each other between kula partners. The armshell or *mwali* is made from shell belonging to the *Conidae*

family. Both ends are broken off and smoothed to leave a cylindrical armlet that is decorated with other shells, seeds, beads, and ornamental items. The armshells travel around the ring in a counterclockwise direction for the necklaces, or *soulava*, which travel in a clockwise direction. The necklace is made up of *Spondylus* and/or *Chama* shell roughly broken and then repeatedly smoothed between stone in a single, long strand of shells strung together to form the necklace. These, too, are highly decorated for aesthetic purposes. While armshells and necklaces are the primary objects exchanged in the kula, other valuables and locally produced resources (such as clay pots, greenstone, and ocher) are also exchanged as solicitory gifts.

Although there are local differences, as a general rule men only have kula partners on other islands. A man will have partners on one side of him from which he receives only armshells. He gives these to partners on the other side of him from whom he can expect to receive necklaces. This means that men have to cross the open seas to solicit and acquire their valuables. Kula protocol is all about attraction and persuasion. While Malinowski wrote that kula was a “very simple affair,” anthropologists have since documented the dangerous business of conducting kula. Partnerships are unstable because others desire the shell valuables they might hold and may persuade the trader to give up the shell to someone other than the intended partner. The consequences of this action include suspension of one’s kula career and even death threats. The most valuable shells invite jealousy and accusations of foul play in their acquisition, subjecting holders to attacks of sorcery. While participation in kula offers men status and prestige, it may also bring upon them disgrace and death.

Today kula continues to be a significant exchange between people in the Milne Bay. Indeed, people who now work and live outside of the province continue to conduct kula with others relocated in other towns, cities, and nations as well as with those within the Milne Bay. Instead of traversing the seas on specially constructed, decorated, and magically impregnated kula outrigger canoes, these partners travel by motored launches and airplanes.

Kulturkreise (*culture circle* or *culture center*) is an early 20th-century German diffusion theory based on the belief that a cultural trait evolved in a specific area and then grew to encompass additional societies. According to this theory, the areas in which cultural traits evolved can be identified and the diffusion of the traits can be mapped. The work of Friedrich Ratzel (1844–1904) served as a motivating force for kulturkreise. Leo Frobenius (1873–1938), a student of Ratzel, developed the culture circle theory, and Fritz Graebner (1877–1934), a German ethnologist, utilized this theory in many of his studies on societies throughout the world.

Graebner’s research and publications helped popularize this school of diffusionist thought. While working at the Berlin Ethnological Museum, Graebner wrote about culture circles in Oceania. Later, he used the kulturkreise theory in a study focusing on the entire world, tracing the spread of an ancient culture’s traditions throughout the rest of the world in his best-known work on kulturkreise, *Das Weltbild der Primitiven: Eine Untersuchung der Urformen Weltanschaulichen Denkens bei Naturvölkern* (*The World View of Primitive Peoples: An Investigation of Archetypal World Outlook Thinking of Aboriginal Peoples*). The methodology outlined by Graebner served as a stimulus for later field research and led to the development of the culture-historical school of ethnology in Europe.

The goal of kulturkreise was to trace cultural traits from their specific origin through their spread to other cultures. It was believed that all cultural traditions originated within a few cultural centers, then spread through increasingly large circles to encompass additional cultural areas. The original cultural centers

were thought to contain discrete characteristics referred to as a culture complex (*Kulturkomplex*). Once the culture complexes were identified, the spread of culture could be traced.

Kulturkreise contrasted with the British school of diffusion thought associated with G. Elliot Smith and William Perry. The British school believed that ancient Egypt was the site for the development of the primary characteristics of modern civilization, and that the modern cultures that retained the civilized traits of ancient Egypt were the most evolved.

German-born Franz Boas, the founder of American anthropology, brought ingredients of the kulturkreise theory to the United States; however, he and other American anthropologists recognized the failures of the kulturkreise theory as a whole and instead focused on the development and diffusion of cultural traits in their historical context to identify connections between different cultures and their traits.

Diffusionist theories gradually lost fashion in anthropology and were replaced by the development of functionalist and structuralist theories. These forms of diffusion are viewed as extreme and not used by scholars today; however, anthropologists do acknowledge diffusion as a source of culture change.

!KUNG BUSHMEN

Strictly speaking, the !Kung are members of a Khoisan language family occupying the Kalahari regions of part of Namibia, Botswana, Angola, and

Zambia; however, the term has come to be used conventionally to refer to the forager peoples of the Western Kalahari surrounding the border between Namibia and Botswana. Specifically, the term is often applied to the Ju/'hoansi—a forager group belonging to the !Kung language family. The confusion over this set of nomenclature stems from changing trends in political preference both among !Kung-speaking peoples and anthropologists. For the sake of continuity, the term !Kung will be used here in its older, conventional sense.

For several reasons, research concerning the !Kung was extremely important within the ecological anthropology of the second half of the 20th century. First reason is the idea, which even extends as far back as early Enlightenment thought, that foragers are somehow closer to nature or to some original state of humankind. This idea was very important to foundational cultural ecologists such as Julian Steward, and also to contemporary anthropologists dealing with issues of human evolution. The second important reason was the understanding that humans had evolved as foragers and had lived with that economic lifeway for the vast majority of human history. For these reasons, there was a great deal of interest in the !Kung and other Kalahari foragers as possible evolutionary models.

Evolutionary Models Based on the !Kung

The earliest major anthropological research in the Kalahari was done by members of the Marshall family. Beginning her second career as an anthropologist in the 1950s, Lorna Marshall offered early descriptions of !Kung economic and social behavior. Most important among these were her early accounts of sharing and reciprocity networks, which became a key long-term research focus among the !Kung. Marshall depicted the !Kung as gentle and nonviolent people living in peace, with egalitarian social and economic practices and no differentiation in status between individuals. She saw a society in which all economic resources were shared, accumulation of resources was not tolerated, and status differences were quickly and forcefully diffused. Despite this somewhat utopian flavor, Marshall's ethnography was excellent in its detail and extremely influential in its effect on contemporary anthropologists dealing with foragers. In addition, her accounts influenced a great deal of the evolutionary thinking of the 1960s and

established food sharing as an important feature of early hominid evolution. Filmmaker John Marshall captured vivid images of the !Kung that became prominent features of anthropology classrooms around the world for decades, further securing the place of !Kung as evolutionary models even in the minds of lower-level students. John Marshall filmed his important images of the !Kung over a long span of time, documenting the changes in !Kung culture during this time. Thus the Marshalls established the persistent and popular image of the !Kung as isolated, autonomous, egalitarian foragers living in a manner very close to the earliest humans. Harvard physical anthropologist Sherwood Washburn, in the latter part of his career by the 1960s, was also important in promoting forager research in order to document analogues with which to understand the past and build evolutionary models.

Due to this early information, a generation of ecological and evolutionary anthropologists made their careers working with the !Kung in the Kalahari. Perhaps the most prominent of this generation was Richard Lee. Working under the direction of Washburn's student, Irven Devore, Lee went to the Kalahari to gather information concerning the economics and social organization of foragers to use as a baseline in formulating a synthetic model. Lee elaborated on Marshall's description of the !Kung as having an egalitarian social and political structure, focusing on the strong sharing and leveling norms of the !Kung. He saw these features as ways of dealing with economic dynamics of the forager lifeway. Lee viewed sharing as a way of coping with resources, such as large animals that are cooperatively hunted and too large to be consumed by individuals of close kin units. During this time period, Lee saw this egalitarianism as a feature of all forager societies, a feature also evident in models of human evolution during the 1960s. These ethnographic features of the !Kung continue to figure prominently in current discussion.

Lee's work in the Kalahari was the cornerstone of the important *Man the Hunter* conference convened in Chicago in 1966. Lee and Devore put together the *Man the Hunter* conference with the idea of establishing hunter-gatherers as a cultural type defined by a fixed set of cultural features. This conference brought together the elite scholars working with foragers either archaeologically or ethnographically, and has had a long-lasting impact on the field. Lee and Devore sought to establish the view of all

hunter-gatherers as egalitarian, with strong sharing and leveling norms and extensive reciprocity networks—a view taken directly from ethnography of the !Kung. This kind of forager research (and particularly that among the !Kung in the Kalahari) came to constitute a paradigmatic industry within the anthropology of the 1960s and 1970s. The model that emerged stated that humans evolved from early australopithecines through the increased hunting of large animals, which stimulated social food sharing, more complex social organization, larger brains and other anatomical changes. This relationship between hunting, food sharing, and complex social organization stemmed directly from these early ethnographic accounts of the !Kung.

The central features of the !Kung economic and social systems that continued to be elaborated upon were the prominent egalitarian sharing and leveling mechanisms and food sharing practices. In particular, a great deal of attention was paid to the *xaro* reciprocity networks; this topic was addressed notably in the research of Polly Wiessner. *Xaro* networks were pathways along which prestige items (jewelry, arrows, etc.) were exchanged, denoting important relationships in terms of individual group membership, residency, and access to resources. Wiessner argued that these exchange pathways, sharing and leveling practices, and food sharing were ways of managing the risk inherent in the forager lifestyle. For example, foragers are susceptible to resource shortages, and hunting is a risky economic practice prone to frequent failure. In addition, successful hunts result in the acquisition of meat packages too large to be consumed by individuals or strictly kin units, and therefore can sensibly be shared. Finally, sharing is the logical outcome of corporate labor practices such as hunting. Shared labor investment results in sharing of the final product. With these explanations as central features, the egalitarian sharing practices and reciprocity networks of the !Kung became vital aspects of evolutionary theory.

Revision and the Kalahari Debate

The direct analogy of the modern, living !Kung with the earliest time periods of human evolution was not without its political problems. By the early 1980s, an important critique was emerging. Critics such as Carmel Schrire, John Denbow, and Ed Wilmsen suggested that !Kung were not isolated, but instead had

been incorporated in regional economic networks for thousands of years. In addition, the !Kung were not autonomous, but had actually been exploited by neighboring ethnic groups in varying degrees over the last several millennia. Finally, they suggested that the !Kung were not entirely foragers, but had lived with mixed economies in relationships with neighboring groups in the past. The critics argued that evolutionary models based on !Kung ethnography were problematic in the sense that they promoted an image of primitive backwardness, or “fossils” of Stone Age. In short, these critics suggested that much of what anthropologists like Lee were describing as innate features of forager peoples were, in fact, the result of historical relationships, and were actually symptoms of rural poverty.

The debate that ensued (often glossed as the “Kalahari debate”) was acrimonious and divisive among anthropologists working with the !Kung. Lee and his followers continued to promote the !Kung as forager analogues appropriate for interpretation of the past. Wilmsen and his followers continued to reject this practice on both intellectual and political grounds. From this context, most recent studies have focused on variability and diversity among forager groups, particularly the !Kung. Prominent among this set of researchers was Susan Kent, who argued that using the !Kung as a kind of modal forager society denied the variability inherent among all foragers. Instead, she argued, it is more productive to document this variability, understand its causes, and use this knowledge to understand variability in the past. This approach is also advocated by Robert Kelly and Lewis Binford in their recent synthetic volumes concerning forager societies. The !Kung continue to be incorporated into evolutionary models, but not as direct analogues or fossils of the human evolutionary past.

Current Lifeways

Today the !Kung live mainly in Namibia and Botswana, incorporated into global economic networks. In Namibia, the !Kung participated as soldiers in the Namibian war for independence, drastically changing their economic systems and dramatically increasing the importance of cash economics. The !Kung fought mainly on the South African side of the conflict, and this provided a considerable amount of cash income to numerous !Kung men who chose to

participate. Following the end of the war, despite the disappearance of the prominent military incomes, wage labor and cash continued to be primary economic pathways. Currently, tourism and government agencies provide the bulk of employment, and state-paid, old-age pensions inject a good deal of cash into the region. On the Botswana side, where military employment was never present, the !Kung continue to participate in patron–client employment relationships with local Tswana herders in the context of difficult and controversial relationships with the government. Nongovernmental organizations (NGOs) on both sides of the border provide important resources, and many anthropologists have important relationships with these NGOs. Finally, foraging continues to be an important practice for both economic and cosmological reasons despite the important role of cash economics. In many respects, future prospects look bleak as the !Kung are confronted by a lack of economic development and increasing dissolution of foraging opportunities in the context of Third World African poverty and global economic systems.

Kwakiutl is the name given to the people of one of the tribes of British Columbia who know themselves as the *Kwakwaka'wakw*, and have five dialects to their Kwak'wala language that stems from the Wakashan phyla. The Kwakiutl are concentrated on the northern end of Vancouver Island, and have constructed a communal lifestyle, for the most part, living on the fringes of the boreal forests. The Kwakiutl developed knowledge of the taking and use of salmon and cedar. From

the plentiful cedar, the Kwakiutl made clothes, houses, ceremonial regalia, baskets, storage and serving utensils, canoes for transportation, and totem poles (some of the tallest in the world) carved to display family crests in demonstrations of lineage and status.

The Kwakiutl are best known for their Winter Ceremonials called *T'seka*, the potlatches where they competed with wealth, and the Hamat'sa, or Cannibal Dancer initiation rituals. When Europeans arrived in the northwest Americas, mercantilism was promoted and consequently affected every part of tribal lifestyle including clothing, food, transportation, hunting and cooking gear, and the symbols of value within the potlatch. As the ceremonial value or prestige of goods was transformed, the Kwakiutl became infamous for their potlatch wars and related activities. In 1884, the Canadian government enacted a law prohibiting the practice of the potlatch; in 1921, Indian agent William Halliday began arresting potlatch attendants, with sentences to prison for not less than two months. The potlatch artifacts that were confiscated were placed in museums and/or sold. In 1951 the law against the potlatch was removed.

During the generations subjected to “civilization,” some of the culture and the Kwak’wala language fell into disuse.

Lifestyle

Salmon was a food source that not only sustained the villagers through the winter, but also played a role in establishing social technologies that created a people who used salmon and other surplus foods like dried halibut in feasts, coupled with oratory edifying of the known cosmology, which assisted in forming a “moral universe” society. This philosophy both honored and demonstrated a kinship with all life, earthly and supernatural. Much like the Koyukon in Alaska, the Kwakiutl also follow the respectful etiquette of returning the bones of the salmon to the sea after eating, a procedure showing respect to the fish in order to seek favor and to ensure the perpetuation of abundant salmon runs and harvests. In addition to salmon, halibut, and other fish, Kwakiutl subsistence included a variety of berries and crustaceans, supplemented by hunting and digging edible roots. Dried salmon, halibut, and deer were stored in large

amounts to ensure survival through the winter, with winter feasting in mind.

The cedar was of inestimable value to the Kwakiutl, as all parts were utilized: bark, roots, wood, and withes. Wood was the base element for shelter, transportation, totemic displays, and bentwood boxes that held valuables such as blankets, masks, and copper shields. Cedar products were made not only for survival, but also as prestige items used in feasts and potlatches. To obtain the tree that would be best for a long house or canoe required skill in detecting the soundness of a tree; but most important, it required the prayers and intuitiveness to be drawn to the right tree, as the Kwakiutl believed it is the tree that offers itself.

Similar to their northern neighbors, the Haidas and Tlingits, the Kwakiutl were a society of established rank of strict stratification, from the chief at the top, through various ranks from high, middle, and low caste, and then debtors and captured slaves. The complexities of Kwakiutl life included etiquette that was strictly followed, such as the correct procedure of placing food in one’s mouth, how to chew, and other ways to avoid vulgarities. Name, rank, and property were claimed and given during potlatch times. Property consisted of dances, songs, and history of

origins; supernatural ancestors; and masks. Feasts could be held for weddings, memorials with a memorial pole, welcoming, naming of children, and for winter ceremonies. Formal invitations and strict protocols were observed at festivities, not the least of which involved refusing an invitation until the fourth time it was extended. In a competitive potlatch, canoes might be burned, copper shields broken or “drowned,” blankets destroyed, and even slaves killed. In Kwakiutl antiquity there were few potlatches given, for these were costly affairs requiring several years to accumulate enough gifts for payments.

European Contact

New prestige items produced through modern European technology made their way through the barter system into the villages, metamorphosing within the Kwakiutl's spiritual and daily activities. Before Hudson Bay blankets replaced fur pelts in the value system, only the elite could give pelts during a feast due to the special value of the pelt, which was not only the coat of an animal, but also had a spiritual significance representing the power and spirit of the animal. There were strong beliefs throughout the northwest coast tribes that animals also had villages, and without their coat of fur or feathers, they would appear as humans. Fur trade with the Europeans brought the much-coveted “modern” conveniences such as metal, pots and pans, china, clothing, fabric, as well as beads and blankets. Difficult questions had to be answered to adapt the conversion of pelts to the common Hudson Bay blanket, but by the time Boaz met the Kwakiutl in 1886, there was already an established value system surrounding exchange with these blankets of newly bestowed value.

Potlatches captured the imagination of newcomers to the Kwakiutl area, and they became highly

controversial among missionaries such as Thomas Crosby, who experienced culture shock in discovering the customs such as dancing. Crosby expressed the horror of witnessing a man cutting himself during a dance, but also explained how a chief felt that a “white man's dance” of holding another man's wife while dancing was worse. The barter marriage among the Kwakiutl brought the most criticism from outsiders. Although the marriages for young girls were a sham, existing only to build the status of the girl and ending

when the young lady reached her first menses, the practice prompted those such as Reverend Alfred James Hall and his wife to have Girl's Homes built, where girls could live until they were at least 16 years old. The media's interest in the potlatch and barter marriages bordered on sensationalism, which brought even more discontent among the settlers and citizens of Canada. Missionaries were given the task to "civilize" the Kwakiutl and other tribes of the northwest.

Ban of the Potlatch

A law prohibiting the potlatch finally passed in 1885, but alterations to this law were necessary for the courts to be able to act on it. Indian agent William Halliday aggressively sought to destroy the potlatch by the indictment and sentencing of its participants, as well as by the confiscation of any potlatch paraphernalia and statements from the accused that they would never potlatch again. In response, people concealed potlatch locations and camouflaged the distribution of gifts and property under the guise of Christmas or other types of gift-giving events, as well as separating the events of dancing and gift giving in order to stay within the law. In 1951, the Canadian Indian Act was revised (sans anti-potlatch laws).

Kwakiutls Today

The Kwakiutl have succeeded in gaining restoration of some of their confiscated treasures and have built two museums to house them: the Kwakiutl Museum and the U'mista Cultural Centre. Since English had become the dominant language, tribes like the Kwakiutl have been attempting to bring their language back.

Today the potlatches are not only reestablished, but are even increasing in popularity. New canoes are being carved, not just for artistic enjoyment, but also for use in canoe races at festivals and the new trend of canoe voyages. Today, Kwakiutl canoe teams can be

seen training along the coastline, preparing for an annual event inclusive to all northwest coastal tribes that draws pullers (paddlers) from as far as the coast of British Columbia to Washington. Stops are made along the many villages up and down the northwest coast; a different final destination is set each year with a potlatch greeting the pullers when they arrive.

The Kwakiutl have been a historic presence along the northwest coast, with their world-famous potlatching and Hamat'sa secret societies. Today they are translating that traditional role into a positive, contemporary one by sharing their culture internationally through art, stories, language, and history; thereby instilling pride in their tribe and communities and giving them international prominence.

LA BARRE, WESTON (1911–1996)

Raoul Weston La Barre, an anthropologist of wide-ranging interests and great accomplishments, was born in Uniontown, Pennsylvania on December 13, 1911. By high school, he demonstrated the careful scholarship and versatility characteristics of his forthcoming career as a psychological anthropologist. He matriculated from Princeton (1933) and went on to Yale, earning his doctorate in 1937 with a study of the peyote religion. He was subsequently named Sterling Fellow at Yale and worked among the Aymara of Lake Titicaca Plateau and the Uru of the Rio Desaguadero. A Social Science Research Council Postdoctoral Fellowship allowed him to receive psychoanalytic training at the Menninger Clinic in Topeka, Kansas, where his friend and colleague, George Devereux also studied.

In 1939, La Barre married Maurine Boie, a social worker and editor of *Family*, a social work journal. She later taught at Duke University Medical Center until her retirement. World War II interrupted La Barre's teaching at his first post, Rutgers University. He joined the Navy as a parachutist trained for naval intelligence but spent two years in China (again, with George Devereux) and Kandy, Sri Lanka. After the war, La Barre, as a Guggenheim Fellow, studied the Japanese and the Chinese and joined the faculty at Duke University.

La Barre's fieldwork had begun in 1935 with the study of the Kiowa of the Plains. These works concerned peyote, on which he wrote *The Peyote Cult*, which has been reprinted and revised numerous times and remains a standard work on the subject.

La Barre's ethnobotanical interests continued in studies on Kiowa folk medicine, Aymara *materia*

medica, and potato taxonomy. These developed into both descriptive and theoretical writings on Native American hallucinogens and the relation of these to ecstatic religious experience in both the Old and the New World. The works predated the interests of medical anthropology and cognitive anthropology by several decades.

A central perspective in La Barre's work beginning in the 1930s was the application of psychiatric—especially psychoanalytic—insights to ethnography. He wrote on the importance of socialization for the development of ethics and the elements of the same that we find in folktales and myths. Despite his orthodox analytic perspective, La Barre emphasized holism in anthropology, as indicated by his classic 1954 work, *The Human Animal*. Here, he showed how specific human traits such as language, family, and culture were reciprocally related to the specific biology and evolution of the human species. He later continued this theme and argued for the role of human biology in religion and even gender. In his 1970 classic, *The Ghost Dance*, he argued that religion's origins must be sought in its creators, human beings, and their experiences of socialization and society, a theme to which he returned in his last book, *Shadow of Childhood* (1991).

La Barre's view of humans was akin to Pareto's at the end of that theoretician's career; much that is human is irrational, especially the sacred. This view is exemplified through his 1962 work *They Shall Take Up Serpents*, which discerned psychopathic and sexual elements in a rural U.S. snake-handling religion.

La Barre's range of interests and expertise allowed him to write insightful articles on a wide range of subjects, such as social guides and the cultural bases of emotions and gestures, as well as ritual public confessions, nonverbal communication, the history and ethnography of marijuana, folktales, and the cultural

relativity of obscenity. He also published articles on family, children, and socialization.

He retired from Duke University in 1977 as the James B. Duke Professor of Anthropology. In the 1980s, La Barre remained active, publishing three books in five years. His final work, *Shadow of Childhood*, appeared in 1991, signaling a publishing career that spanned more than five decades. His publications now occupy more than 7 linear feet of shelf space in the National Anthropological Archives at the Smithsonian Institution. He was also, perhaps, anthropology's most precise English-language writer, with examples from his writings cited for correct usage 138 times in Webster's *Third International Unabridged Dictionary*. His life partner Maurine Boie predeceased him, and La Barre died in North Carolina in March, 1996.

LABOR

Labor involves purposive effort, mental or physical, toward a goal. In studying labor, we should be particularly careful not to import the biases of our own economic culture. Labor is not always clearly segmented from other activities in daily life, although the wage labor system favors such segmentation; this confusion obscures unpaid labor within capitalism as well as work in noncapitalist settings. Likewise, we need to be careful not to extend male gender biases to the study of labor; child care is as much labor as is cutting hay. Finally, we need to include multiple

dimensions of labor, such as ideas and social organization, as well as physical effort, and we need to pay corresponding attention to nonstereotypical instances of work and workers, for example, bureaucrats as much as miners.

Labor is a central characteristic of human life; indeed, a number of scholars have proposed it as the defining characteristic, one that has shaped human evolution and history. David Ricardo and other early economists proposed a labor theory of value, and Karl Marx and Friedrich Engels made labor central to their theory of society as well as to their revolutionary politics. They viewed labor broadly, as active engagement with the natural and social world, and saw it as integral to human species. However, labor's products and value became separate from the humans who made them with the development of commodities, class society, and especially wage labor capitalism. The past results of labor, taken and used in the form of capital, then confront current labor as an alien and powerful force.

A number of anthropologists, such as Lewis Henry Morgan (who influenced Engels), similarly saw labor, or its close associate tool use and technology, as central to cultural evolution. Even as 19th-century evolutionary schemes faded, labor continued to be a central concern of anthropology. Many scholars saw tool use as central to the evolution of the brain. Julian Steward's combined approaches of cultural ecology and multilineal evolution focused on work, as Robert Murphy has noted. Steward's notion of the culture core was the social organization of labor in food production within a particular environment.

Important insights were achieved in grand theorizing about labor, but its importance was exaggerated. In hominid evolution, for example, bipedalism preceded well-formed tool manufacture, and social organization and language use must be accorded equal evolutionary importance to labor (although all are interrelated). Likewise, in the findings of cultural anthropology, expression and imagination balance purposive labor. The human condition combines work and release, discipline and antidiscipline, production, reproduction, and play, and no single view seems adequate.

Labor in small-scale societies is tightly integrated with the rest of daily life. Gathering, for example, takes place along with child care and socializing, and it produces an immediate product for consumption rather than a product to be stored and alienated from

the producers. The gender division of labor, along with age, largely organizes small-scale production, but as with so many human phenomena, flexibility and variability are the rule; most hunters are men, but there are female hunters, and gathering is done by males as well as by females (similar comments can be made about horticulturalists).

Time allocation studies have been particularly influential in the study of labor, and their striking result is that people in small-scale societies work significantly fewer hours than do people in industrial societies filled with “time-saving” devices. In fact, increased time spent in labor is a sensitive indicator of greater social inequality because labor goes to provide not only for the person and immediate dependents but also for a wider social structure of surplus takers and a vast apparatus of technology.

This is seen clearly as we move to unequal agrarian societies. In some ways, there is continuity with small-scale cultures, for example, in patterns of direct production for use. However, Eric Wolf used an analytical framework of peasant “funds” to identify the uses of labor’s products—subsistence, replacement funds, and ceremonial funds directed to peasant needs and goals as well as funds transferred to others as “rent” (including taxes and unequal market relations as well as payment for land as such). The question of transfer of the product of labor becomes more central yet with wage labor capitalism. In this context, some labor (physical and mental) is segmented from the rest of life, used to create commodities for an employer, and then turned into money and, in turn, into other commodities made by yet other workers. In the process, direct production for use declines (but by no means disappears, as feminists have shown for housework), and the accumulated past product of labor—or capital—has power over current laborers.

Engaging this range of settings, a rich anthropology of work has emerged. There have been numerous ethnographies of industrial workers, with June Nash’s study of Bolivian tin miners notable for showing connections between seemingly disparate preindustrial and industrial cultural frameworks. Sidney Mintz provided a superior life history of a Puerto Rican plantation worker and later explored, in the case of sugar, global connections between commodity production and commodity consumption. Ethnographers often reveal hidden, informal social organization and implicit knowledge among workers, exemplified by

Herbert Applebaum’s study of construction workers and Frederick Gamst’s ethnography of locomotive engineers.

Recent work has examined light manufacturing of consumer goods for global export in Mexico (by María Patricia Fernández-Kelly), in Malaysia (by Aihwa Ong), and elsewhere. Carla Freeman explored the emerging global trade in white-collar services and, in so doing, highlighted the management of self required by such industries. The sociologist Arlie Hochschild opened up an important line of inquiry into caring work, including both paid and unpaid caring for children, the elderly, and the ill, raising important feminist questions about the cultural frameworks surrounding contemporary labor, and Josiah Heyman explored the labor of consumption (again with a gendered perspective) seen as the production of daily life within commoditized societies. Clearly, the list can go on because labor is indeed fundamental to human existence.

LABOR, DIVISION OF

Anthropologists refer to the division of labor as the different tasks that people do to provide for their physical needs and to reproduce their culture. We base these tasks on such criteria as age, gender, and skill. How this division is manifested varies across cultures and according to societal type.

In the foraging, tribal, and peasant societies, labor tends to divide along gender lines. Among foragers, such as the !Kung, men hunt large game animals, while women collect wild edible plants and care for

children. Within tribal societies such as the Yanomami, women keep garden plots and care for children, while men engage in hunting and trade. Among peasants in Latin America and Asia, men tend to farm and women manage the household. In these societies, there is little specialization in that a man or a woman does just one job, although they learn most of the tasks that their respective gender does.

Among people living within state societies, in contrast to foragers, tribal people, and peasants, there is a high degree of job specialization. From farmers to craftspersons, government administrators to cooks and teachers, men and women dedicate their labor to one specific task. In industrialized societies, a person can specialize even further by making only a component of a product rather than the entire product. Service industries are similarly divided into multiple tasks. In these societies, members cannot learn all the jobs that are performed, but there are fewer gender- and age-based divisions of labor.

This deceptively simple definition belies both the complex classificatory practices used by earlier ethnographers as they described how people provide for their needs and wants and the diverse analytical practices used by contemporary ethnographers studying why people do the tasks they do. Anthropologists have long recognized that human beings divide their labor into distinct tasks according to age, gender, kinship, skill, and knowledge. Classic ethnographies by Bronislaw Malinowski, A. R. Radcliffe-Brown, and Margaret Mead contain obligatory chapters explaining the division of labor within a structural-functionalist framework. In such ethnographies, the ways in which labor is divided illustrates how labor functions to reproduce the members and culture of that society.

In more contemporary ethnographies, anthropologists have moved away from the mere classification of the division of labor and functionalist explanations. Instead, anthropologists study the division of labor by analyzing why people do the jobs they do. They aim to show how people work within their respective societies and across diverse cultures and to learn why the division of labor in society changes.

In part, this line of research grows out of Adam Smith's 1776 book, *An Inquiry into the Nature and Causes of the Wealth of Nations*. A proponent of industrialism, Smith argued that, not only does the division of labor increase productivity, the specialization of tasks into subtasks makes the workers more

productive and allows them to increase their skills. By focusing on a particular subtask rather than the whole task, workers are more efficient and contribute to a superior product.

Early anthropologists such as Herbert Spencer in *Principles of Sociology* combined Smith's analysis with evolutionary perspectives of societal change to argue that, as individuals compete for jobs and compete to improve the products they make, societies would progress from simple to complex. Civilization, as conceived of by Americans and Europeans in the late 1800s, is the ideal. Along the way, a new, more efficient division of labor would replace the division of labor in less complex societies.

More contemporary anthropologists who study the division of labor may be influenced by the theoretical perspectives that Émile Durkheim presented in his 1983 book, *The Division of Labor in Society*, and those that Karl Marx and Friedrich Engels presented in works such as *Capital* and *The German Ideology*. Both Durkheim and Marx were concerned with how industrialization and increased commodification affected society. Although they shared Spencer's evolutionary theoretical orientation, they did not agree that industrialization would necessarily lead to utopia, but in a contrary direction.

Durkheim argued that society helps maintain order and keep individuals' self-interests and desires in control. In societies characterized by mechanical solidarity, such as the !Kung, members are integrated according to likeness: moral ideology, nonoccupational specialization, and kinship. In those characterized by organic solidarity, however, such as the industrialized United States, members are not well-integrated and differences and divisions are more common among individuals. The causes for this are a division of labor in which there is greater specialization. Unlike the division of labor within societies based on mechanical solidarity, those based on organic solidarity lose their moral bonds and sense of community.

Marx and Engels also believed in the destructive nature of industrialization. They focused on the material conditions of human labor to show how increased specialization and commodification contributed to the development of social classes and caused workers to develop poorer skills overall and to lose their pride in their work. In other words, these workers' labor is alienated from the item being made because they learn only some small part of the

process. Marx did regard the division of labor as a necessary form of cooperation, but it is within a commodity-driven society that the divisions of labor are deleterious to the well-being of individuals and ultimately to that society itself.

These theoretical perspectives have influenced a great number of anthropological studies that question the relationship between work and culture, the nature of social classes and class struggle, and the links between work and gender roles. In particular, the analysis of the division of labor according to gender has helped transform how we think about why women and men do the tasks that they do. In *Sex and Temperament in Three Societies*, Mead showed that the division of labor by gender varies from society to society, dispelling Western cultural biases about the supposedly natural jobs that men and women do to maintain their material bases and cultural practices. Later, feminists Louise Lamphere and Michelle Rosaldo used Engels's work, *Origins of the Family, Private Property, and the State*, to question the ways that capitalism and industrialization have changed the gendered division of labor. The biases they describe about what we consider woman's work and how labor benefits are culturally and materially allocated in favor of men are also discussed by Ruth Behar and Deborah Gordon in *Women Writing Culture*.

From early anthropological descriptions of the tasks that people do from society to society to maintain their culture, anthropological research on the division of labor has progressed to analyses that ask why people do the tasks they do, who does them, and how they are rewarded.

LAFITAU, JOSEPH-FRANÇOIS (1681–1746)

Joseph-François Lafitau was an important French Jesuit missionary scholar who closely observed the Mohawks and other Indians at the Jesuit mission of Sault-Saint-Louis opposite Montreal during the early 1700s. Social theorists describe him as a proto-anthropologist because he combined critical use of historic sources with careful (albeit not always accurate) use of the comparative method, with an insistence on the dignity of Native beliefs and the worthiness of their study. Lafitau's work remains a vital ethnographic source for anthropological study of Iroquois people and of the history and culture of the Jesuits and their missionary endeavors.

Born in Bordeaux, France, in 1681 to Jean Lafitau and Catherine Berchenbos, both Joseph-François and his brother Pierre-François became Jesuits, members of a religious order of men founded by Ignatius of Loyola in 1540 that quickly garnered a reputation for intellectual acumen as well as pedagogical prowess. Beginning Jesuit formation in 1696 at 15 years of age, Joseph-François completed his 2-year novitiate and then went on to studies in philosophy, rhetoric, humanities, and theology as well as assignments to teaching posts and engagement in other apostolic duties by 1711.

While his brother was eventually consecrated bishop and never left Europe, the newly ordained Joseph-François requested assignment in New France and took the rigorous ocean voyage in 1712. He did his tertianship (final year of formation) in New France and took final vows in Montreal in 1716.

Lafitau worked among the Mohawks for roughly 6 years (1712–1717), allowing him time to master the language adequately, to gain familiarity with the local people, and to hone his observational and interview skills. In all this, he anticipated anthropology's defining methodology of fieldwork using the local language. He studied the *Jesuit Relations*, a contemporary compendium of reports by Jesuit missionaries in New France that contained considerable ethnographic detail concerning Native peoples. He also learned from the veteran Jesuit missionaries in the field, especially Julien Garnier, who had labored 50 years with the Iroquois. His intensive Jesuit training in Christian and Hebrew Scriptures, Greek and Latin Classics, and

mission reports from throughout the world provided ample material for his comparativist project.

Lafitau's most important contributions, achieved through careful and prolonged observations, elucidate Iroquois architecture, matrilineal descent, classificatory kinship (later rediscovered by Lewis Henry Morgan, who was not familiar with Lafitau's work), clan exogamy, the relationship of age grades and social status, and the significant role of women in Iroquois political life. While not always giving a proportional treatment to topics in his *Customs of the American Indians*, he considered the origins of the Indians as well as their religion and mythology, politics, marriage, occupations of men and women, dress, war and weaponry, trade, hunting and fishing, games, illness, medicine, death and burials, and finally language.

Cognizant of the great changes in Iroquois culture with the arrival of Europeans, Lafitau engaged in what was later called memory ethnography to reconstruct precontact lifeways, a preoccupation of 19th- and early 20th-century salvage anthropology. Although Lafitau was certainly not the first to compare Native American cultures with those of classical Europe and the Middle East, he did refine the method by critical use of written sources and direct fieldwork.

Returning to France in 1717, Lafitau urged that the mission be relocated due to soil and natural resource depletion, and he advocated the abolition of the liquor trade. He became mission procurator 1722 and was charged with providing for the financial and physical needs of the missions of New France. He held that office for 19 years. Reconnected with the libraries of Europe, Lafitau also used this time to write. First, in 1718, came a treatise on ginseng, which he learned about from a female Mohawk herbalist near Montreal, also drawing on European published descriptions (thereby becoming an early ethnobotanist). Next, in 1724, he turned his attention to what became his most important work, *Customs of the American Indians*, and also published *Historie de Jean de Brienne, Roy de Jérusalem et Empereur de Constantinople* in 1727. He returned to Montreal between 1727 and 1729 to serve as mission superior. Returning to France, he published his final book, *Histoire des découvertes et conquêtes des Portugais dans le Nouveau Monde*, in 1733. Lafitau also revised his very large chapter on religion, although the revision was never published. He died in the city of his birth in 1746.

Outside Jesuit and Catholic intellectual circles of the time, Lafitau generally was unnoticed or even opposed. He came to prominence during the 20th century when his unique contributions to the history of anthropology were recognized in France by Arnold Van Gennep, in Germany by Wilhelm Schmidt, and in Anglophone England and the United States by luminaries such as Francis Parkman, John Cooper, Anthony Reginald Radcliffe-Brown, Margaret Hodgen, Sol Tax, Meyer Fortes, and Lafitau's most important biographer William Fenton. Although his theological premises, universal comparisons, and ethnocentric peculiarities are rejected by contemporary anthropological method, Lafitau remains an important early practitioner of the discipline of anthropology.

Father John M. Cooper, himself a priest and ethnographer of the Gros Ventre of Montana, in 1935 wrote the early short biography that brought Lafitau to the attention of contemporary English speakers. A deep appreciation for the historical and ethnographic importance of Lafitau's life and works prompted William Fenton (a scholar of Iroquois culture) and Elizabeth Moore to translate into English Lafitau's *Customs of the American Indians Compared With the Customs of Primitive Times* in 1974, adding an extensive introduction to Lafitau's life and his significance as a recorder of Iroquois culture and within the history of European intellectual development as well as illuminating footnotes. William Fenton also wrote two earlier biographies of Lafitau in 1969 and 1974. The Champlain Society recently issued a free electronic version of this work. In 1971, Margaret Hodgen wrote on Lafitau and other proto-anthropologists of his era and provided historical context for these seminal thinkers. The 2002 work of Jesuit Father Carl Starkloff, a theologian who also worked closely with Indian tribes in Wyoming, demonstrated the currency of Lafitau's thought for missiological and theological questions.

LANGUAGE

Language, like culture, is something that is easier to discuss than to define, and no unitary definition is offered here. Instead, what anthropologists and linguists mean by language is better understood by trying to be clear about what does and does not count as language. In some cases, this involves disentangling folk uses of the term *language* from scientific uses.

In its folk sense, language is often used to mean any communication system—the “dance” of honeybees, the significance of type and color of flowers given to someone, computer codes, the posture and gestures included in “body language,” and so on. Although these are indeed communication systems, they are not examples of language because they lack specific properties of human language, including especially the following:

Discreteness or discrete infinity. The elements of language (phonemes, words, and phrases) are perceptually discrete and can be combined and recombined without limit.

Dual patterning. A relatively small number of phonemes (as few as 15 for Hawaiian and approximately 35 for English), which are without intrinsic meaning, are combined to form units that bear meaning (e.g., morphemes, words). In other animal systems, each call is a meaningful unit.

Hierarchical structure. Linguistic elements are nested within each other. For example, the noun phrase *the gray cat* contains the nested constituents *the* and *gray cat*, and *gray cat* in turn contains *gray* and *cat*.

Structure dependence. The rules that govern the formation of words, phrases, and sentences operate on structural categories such as nouns and verb phrases, not on individual words such as *cat* and *eat*.

Some features of human language that are hinted at in other animal communication systems include the following:

Displacement. Linguistic expressions can have referents that are not present in either space or time such as the moons of Saturn and Attila the Hun.

Prevarication. Linguistic expressions can have referents that exist only in the imagination such as Tolkien’s hobbits and Darth Vader.

The displacement feature may be present in the communication of direction and distance to the source made by honeybees. In addition, many animals “lie” by disguising themselves as more dangerous animals. Some monkeys learn to give false warning calls to the troop when they are under threat from other monkeys, and some of the primates that have acquired elements of human sign language seem to be able to use it for both displacement and prevarication, although they appear to be proficient at about the level of a 2-year-old human.

For anthropologists and linguists, then, one sense of language is the species property, the apparently uniquely human and innate capacity to acquire and use the entities that we label with words such as *English*, *Tagalog*, and *American Sign Language*. Darwin called this our “instinctive tendency to acquire an art.” This is not an entirely uncontested view, but most linguists agree that language is innate in humans, although all agree equally that the specific language variety that people acquire as children depends on the social context within which they are enculturated.

Studying Language

Scholars who study the structural aspects of language generally focus on one or more of the traditional core areas: phonetics, phonology, morphology, syntax,

semantics, and pragmatics. These core areas represent most of what users of a language must know about their language:

Phonetics. Speakers must know how to articulate the sounds of their language. English speakers must know that the first sound of a word such as *top* is alveolar rather than dental as in Spanish.

Phonology. Speakers of a language must know what the distinctive sounds of their language are. English speakers must know that the sounds [p] and [b] contrast in words such as *pat* and *bat*.

Morphology. Speakers must know how to combine the sounds of their language into meaningful units—words, prefixes, suffixes, and so on. English speakers must know how to form the plural of words such as *cat*, *dog*, and *bush* by adding the appropriate suffix to form *cat[s]*, *dog[z]*, and *bush[iz]*, respectively.

Syntax. Speakers must know how to combine their words into sentences that call attention to something and then provide information about it. Again using English as an example, English speakers must know how to form yes/no questions from statements such as “She is in the kitchen” (“Is she in the kitchen?”) by the appropriate movement of *is*.

Semantics. Speakers must know the meanings of the words they use. Speakers of English must know that *foot* refers to a small part of the leg, whereas speakers of some forms of Creole English must know that *foot* refers to the entire leg and foot.

It is also possible to study how people use their language appropriately to accomplish what they want in a given social situation (pragmatics), how language shapes and is shaped by social context (sociolinguistics), the acquisition and mental processing of language (psycholinguistics), language variation across space or between social groups (dialectology), and language variation through time (historical linguistics).

The knowledge that native speakers have is mostly unconscious knowledge; they “know” how to use their language, but they (usually) cannot explain how or why they say what they say. The scientific description and explanation of this knowledge, as possessed by a language’s native users, is known broadly as descriptive grammar. In its folk sense, however, grammar often refers to prescriptive rules of use that are, in fact, social rules rather than linguistic rules. One example is the rule against using double negatives in English. Like most such rules, this one wrongly took language to be a logical (rather than a patterned) system. Prescriptive rules sometimes try to make one language fit the patterns of another more prestigious language such as the Latin-inspired rule against ending English sentences with prepositions. Still other prescriptive rules attempt to impose social values on language such as the English rules promoting *man* and *he* as “generic” forms.

Language, Dialect, and Idiolect

In another folk sense, language refers to any of a number of entities with labels such as *English* and *Tagalog*. But these are really labels of convenience; what counts as English is contestable within a socio-cultural context. The points at which language can be thought of as a natural object are (a) the linguistic knowledge possessed by individual persons (their idiolects) and (b) the property universal to the human species, namely human language. In between these

extremes, entities such as “English,” “American English,” and “African American Vernacular English” are fuzzy categories that are socially and culturally defined and whose membership may expand or contract, depending on social and cultural consensus. They are all “dialects” because, at different levels, they all represent forms of language acquired and used across speech communities.

Because all people speak dialects, the reasons why particular forms of language get labeled as languages and others get labeled as dialects must be sought in the context in which they are embedded. The people who wield political, economic, and social control speak the “language”; nonelites speak a “dialect” of the language. As the old linguistic saying suggests, “A language is a dialect with an army and a navy.”

Language as Biology and Culture

It seems clear that language is a part of the human biological endowment. Perhaps the most compelling evidence for this can be found in the area of children’s acquisition of language. All normal human children everywhere acquire the language of their social setting at about the same pace and in the same way. They do so without formal training, and they do so in social and cultural contexts that differ in terms of what kinds of linguistic interactions are supposed to be appropriate between parents/caregivers and infants. These differences do not seem to affect the rate or quality of children’s acquisition of language; in a sense, children acquire language in much the same way as they acquire the skill of walking. However, children who for some reason are isolated from all forms of linguistic interaction do not acquire language, and if they reach puberty without exposure to language, they might never be able to acquire more than a very rudimentary linguistic ability.

By the time children are roughly 3 to 4 years of age, they have mastered some of the most complex and subtle rules of their language, rules that no teacher of language could ever teach them. Of course, they still have lots of vocabulary to learn as well as some of the pragmatic rules of language use in different social situations and the literacy practices of their culture.

Although the underlying shape of language is biological, any given language itself is a cultural artifact. The best way of illustrating this is to take the words for the domesticated animal that English speakers refer to as a *dog*. All languages have a word for this

animal; no language has a word for “half a dog.” This seems to result from a property of the human brain that guides our perception and representation of natural objects in the world, such as dogs, that come to us in whole “packages” (other candidates might be rocks, trees, birds, and so on). At the same time, the words we find in different languages are as different as *dog* (English), *perro* (Spanish), *anu* (Aymara), *kelb* (Arabic), and *sobáka* (Russian). None of these words has a privileged connection to the animal itself. Each is an arbitrary but conventional answer to the problem of naming this familiar domesticated animal.

Apes and Language

Investigators have made numerous attempts to teach our phylogenetically closest relatives, chimpanzees and gorillas, to use language. Early efforts to teach them oral language were unsuccessful due in part to the fact that their vocalization behavior is not under fully voluntary control. Beginning in the 1960s with the chimpanzee Washoe, some of these fellow hominids showed that they can acquire and use a limited subset of a signed language such as American Sign Language, and they have also demonstrated some proficiency with other symbolic systems using computerized images or plastic tokens. Their linguistic capacity seems to limit them to a “two-word” or “telegraphic” use of the signs or tokens, although at least one bonobo (*Pan paniscus*) seems to understand some complex spoken English sentences.

During the formative years of anthropology, the study of language was at the core of ethnology done by researchers such as Franz Boas and Alfred Kroeber. Notions about language developed alongside the broader precept of cultural relativism, under which it was believed that languages, like cultures, could vary infinitely. It was also assumed that language acquisition was primarily a product of external forces. Noam Chomsky’s 1958 review of B. F. Skinner’s *Verbal Behavior* challenged this view by amassing evidence that language acquisition is driven primarily by an innately provided universal grammar and that enculturation fills in the surface details, determining whether a person acquires “Japanese,” “American Sign Language,” or some other system. To account for the fact that human children can easily acquire, without formal teaching, whatever happens to be the language of their community, most of language must be innate and languages must be, at some level, far more alike

than different. Some anthropologists resisted this approach to language, preferring instead to continue focusing on the features that make languages different from each other, in keeping with the broader interest in cultural differences over cultural universals.

NOAM CHOMSKY

Anthropological linguists have closely followed the works of linguist, educator, and political activist Noam Chomsky since the 1957 publication of his *Syntactic Structures* transformed the study of linguistics and launched the "cognitive revolution." Understanding how children acquire language is an essential element in understanding linguistics. Chomsky contends that all children have the ability to learn language without being taught by those around them. He suggests that children learn the basic rules of grammar as they learn to talk without realizing that they are doing so. Unlike animals that are rewarded for language-related accomplishments, children, at least past the infant stage, are not

rewarded for language acquisition, nor are they punished for not acquiring language skills.

Chomsky maintains that bilingual or multilingual children are able to pick up the correct rules of grammar as they learn a language. He also believes that there are universal characteristics in children's acquisition of language. Chomsky's theory was supported by a 2004 study at the National Institute of Child Health and Human Development where researchers studied language acquisition in 269 children from Argentina, Belgium, France, Israel, Italy, the Republic of Korea, and the United States. All children were 20 months old. The study revealed that nouns, verbs, and adjectives, in that order, make up toddlers' language regardless of the emphasis on a particular part of speech in the language as a whole. For instance, English emphasizes nouns, while Korean accentuates verbs. Researcher Marc Bornstein posited that the emphasis on nouns for all toddlers in the study was a response to the tactile nature of objects as opposed to abstract verbs and adjectives that toddlers might have trouble comprehending.

Although linguists have studied language acquisition since the discipline began, the exact meaning of sounds that preverbal babies make has remained a mystery. In early 2005, researchers at the Infant Language Lab of the James Whitcomb Riley Hospital for Children and the Indiana School of Medicine announced that they hoped to solve this mystery of language acquisition in order to

develop tools for teaching deaf infants, who have received cochlear implants, how to talk. Cochlear implants are small electronic devices that are used to magnify sound for individuals who are either deaf or severely hard of hearing. According to the National Institute on Deafness and Other Communication Disorders, approximately 10,000 children in the United States have received cochlear implants. The majority of these children received the implants between the ages of 2 and 6.

Researchers Derek M. Houston and Tonya R. Bergeson are developing methods to test comprehension levels of infants in order to discover how infants process language. This information will be used by speech therapists to work with deaf infants as they discover the world of sound. In the past, researchers have been unable to test the language perception of children less than 2 years of age. Possible ways of testing infant language perception include tracking eye movements, recording information on responses to stimuli, and noting the length of time an infant stares at objects. Infants in the study are placed in a darkened room with a parent, as an unobtrusive camera above their heads tracks their responses.

While the focus of the study is identifying the differences in the way that hearing and deaf children with cochlear implants respond to sound, in other related projects, researchers are gathering significant data in areas that will enhance the entire field of language acquisition. Researchers are also looking at the seemingly instinctive practice of mother's talking "baby talk" to their infants. Bergeson reports that mothers of deaf children with cochlear implants talk to their children in language appropriate for their hearing age, based on the length of time the cochlear implant has been in place, rather than the child's chronological age.

LANGUAGE AND BIOLOGY

Both the biologist and the linguist are interested in how language evolved in the natural history of the human species. This process was embedded in the

evolution of life from the first self-replicating macromolecules to the wealth of species living today on Earth. The evolutionary thinker hits, therefore, on a more fundamental question: Is human language the most complex realization of abstract principles that govern the processing of every kind of biological information?

But let us start with the first question: How did language evolve in our natural history? There is not a single science that can answer this question; research on the natural history of language is an interdisciplinary project that must bring together linguists, neurobiologists, social anthropologists, and evolutionary theorists, among others.

If we want to find the evolutionary origin of language, we need foremost a theory of what language is so that we can describe the relation between the general language competence of humans and the specific use of all those languages that were, are, and will be spoken in different human populations. A first idea could be that a language is just the set of all sentences that were ever spoken in some population. But how can a sentence be defined without criteria for whether an utterance is a well-formed combination of words? So, we need to know a grammar, which is nothing more than a rule-governed set of such criteria.

The grammars of, for example, Japanese and English do not look at all alike. Has the biological evolution of the human species, therefore, nothing to tell us about today's linguistic variety given that it is a result solely of cultural history and nongenetic transmission? On the contrary, according to one of the most influential linguistic theories, Noam Chomsky's theory of universal grammar, every human inherits the same grammatical competence involving abstract principles of how to learn a language. These principles alone cannot determine the language a child will learn; they contain parameters, the values of which are set by the social environment of the child, so that the rich variety of languages is generated by different individual experiences.

What is innate, and what is acquired in the knowledge of grammar, can be decided only by empirical research, in which human biology and social anthropology must cooperate. Apart from other research on anatomical and physiological prerequisites for language use, the most important question for the biologist involves investigating the neural structures in the brain that implement the different parts of the linguistic competence—from the phonological

analysis of utterances, through the generation of syntactic patterns and the semantic understanding of words and sentences, to the pragmatic knowledge of what is expected from the hearer when he or she perceives a certain kind of sentence in a dialogue. The neurobiologist must come to an understanding of how the neural instantiations of partial linguistic competencies are ontogenetically formed, and the zoologist must compare them with homologous parts in the brain of kindred species.

Yet language is, even from a strictly biological point of view, a social phenomenon. No human would speak if there were not others with whom a coordination of behavior is necessary to achieve some individual aims by social action. Therefore, primatologists and anthropologists are asked to explain the coevolution of innate cognitive competencies and social contexts in which the biological evolution of language happened.

The last remark draws our attention to possible evolutionary reasons for the origin of language. It seems evident that language provided a selective advantage for the ancestors of the human species in their struggle for survival because it is superior to any other known system of animal communication. But was language directly selected? Or did there exist some other previously selected mental faculties on the base of which the linguistic competence came into being as a kind of cognitive by-product that was only indirectly selected? Although the second alternative is more complicated than the first alternative, which is the typical answer that would be expected from a Darwinian, the creative possibilities inherent in language speak in favor of the second alternative, which is also compatible with the theory of natural evolution by selection. In contrast to any other system of animal communication, each of the different grammatical systems of human language allows one to construct an endless number of well-formed combinations of words and to communicate the same vast number of thoughts. Because this faculty transcends any direct adaptation to immediate communicative needs, the computational power of human language seems to have its origin rather in a kind of interface between sensory-motor and conceptual-intentional systems that were directly functional as adaptations by natural selection.

To this point, our evolutionary considerations seem to conceive language as a general anthropological characteristic that discriminates humans from any other kind of organism, a point of view that would

be in agreement with a long Western philosophical tradition since Aristotle. But although we adopt the thesis that there does indeed appear to be something new in human language in respect to its computational power, we need not deny a second thesis: Human language is the most complex realization of abstract principles that govern the processing of every kind of biological information.

To support this thesis, we must ask whether it is possible to interpret the evolution of life on Earth in general, from the origin of the genetic code through intercellular and neural codes to the evolution of animal communication and of human language, as a history of the discovery and establishment of forms of information processing, which are nothing more than different types of languages. If so, abstract principles governing human language should be found in a more primitive form even on the level of genetic information processing. Since the 1970s, scientists interested in the functional organization of biological information, such as Vadim A. Ratner, Manfred Eigen, and Bernd-Olaf Küppers, have systematically described the linguistic character of genetic information.

Modern genetics conceives heredity as a process of storing, transmitting, processing, and transforming genetic information. To do so, it uses the concept of code for the description of the structure of the material carrier of hereditary factors, the deoxyribonucleic acid (DNA). Let us describe some main features of the linguistic structure of DNA.

- DNA stores genetic information in the sequence of its four nucleotide building blocks that bear no genetic sense separately. Yet they are combined in linear sequences of three nucleotides (called “codons”) that do have a genetic sense. Each codon encodes an amino acid building block of a protein, so that the syntax of codons encodes the linear sequence of amino acids in the polypeptide chain of a protein.

- But if the syntactic structure of DNA can instruct the biosynthesis of proteins, there must exist a set of rules—a code—that attaches an amino acid to each possible codon. Indeed, such a genetic code exists; it defines the semantics of genetic information.

- Like in human language, this genetic semantics is contingent. Although the genetic code is the same in all organisms, the semantic relations of codons to amino acids originated not only in biochemical

necessity but also in evolutionary accidents. To explain the origin of genetic semantics, we must discover the singular boundary conditions of its first use, that is, the primitive pragmatics of genetic information in self-replicating molecules.

Our short remarks show that we can describe a language of genes involving the syntactic, semantic, and pragmatic dimensions of genetic information. If we expand our horizon and analyze other kinds of biological information by linguistic means, we are making a further step toward the integration of human language into a general evolutionary perspective on natural and cultural history.

LANGUAGE AND CULTURE

Attempts by linguists and anthropologists to understand humankind have always focused on two areas: culture and society and language and communication. It is somewhat unnatural, however, to separate the study of language from the study of culture, as doing so can limit attempts to characterize the development of peoples and how they create communities and live in societies. Language and are intrinsically related or, as Agar says in *Language Shock*:

Culture is a conceptual system whose surface appears in the words of people's language.

Culture

In *Language and Social Semiotic*, author Halliday calls culture a social reality that consists of many interrelated

dimensions. A traditional view might characterize culture as a group of people who most likely use the same language, live in the same geographic region, have the same moral and religious value systems, and participate in similar activities. Most researchers would judge this traditional view of culture as incomplete. Just as society is, culture is a complex concept. Anthropologists, linguists, and others have attempted to define culture, but language and communication characteristics are critical to the definition. Individuals do not develop cultures in isolation nor apart from language. Belonging to a culture requires belonging to a group and establishing bonds with members in the group through communication and language interactions. Existing cultures provide the means for individuals to form their personal identities and to make decisions about living, roles, membership, and participation; language is a major player in the development or demise of a culture. It is important to consider the differences between cultures and language use by peoples of the past and cultures and language use that has survived or has developed within current human societies.

Language and its Relationship to Living in Society

Language is more than just a singular component of culture. It is a symbol system that acts as a glue to bind cultures together. Reference to language in relation to most human societies and cultures nearly always involves spoken communication and written language; one notable exception is the culture of deaf individuals, which relies on language that is signed rather than language that is spoken.

The relationship between language, communication, and culture is complex. While language is a powerful and necessary tool to unite individuals in particular cultures, it may act as a barrier or be used to exclude or separate people in a society and within cultures. The author Ben-Rafael, in discussing Zionist immigrants to Israel, explained that, even though these individuals belonged to a common culture, they had migrated from Russia, Poland, and other eastern European countries with varying competencies in languages. Identification with a culture becomes dependent upon prior social context, and the choices of language and language adjustment are not always simple matters.

Members of a Sephardic family who moved from Bulgaria to Israel could speak between two and four languages besides Hebrew, and each member,

especially the grandfather, was determined to speak one of the alternative languages to Hebrew at home. We can assume that immersion into Israeli/Hebrew society affected family interactions as well as their perceptions about their language use in society. Ben-Rafael explained that the grandmother criticized her husband for using Bulgarian because it was a non-Jewish language. And the grandchildren preferred English to Hebrew because it would support their future university studies and help them converse with visitors and during travel abroad.

The Prominent Place of Language

Individuals may speak different languages and belong to the same culture, or individuals may speak the same language and belong to different cultures. Sometimes people may be involved in multiple language groups that influence their choices of cultural identity. The ability to speak a language is not the only determinant for belonging to a culture or participating in a society, but it is intrinsic to establishing social identities and cultural roles.

Different Languages, Same Culture

One population that may be characterized as having more than one language but belonging to a culture of a major society is the deaf community in the U.S. Although a vast number of adults use American Sign Language (ASL) as their mother tongue and choose to belong to a distinct, identifiable deaf community, they are citizens of the United States and

belong to the broader hearing society that uses English as its primary language. Deaf individuals share economic responsibilities, occupations, healthcare, and leisure with the hearing American society and are immersed and involved in American culture at every level.

Over 90% of deaf individuals are born to hearing parents, and more than 83% of deaf children attend public and private schools with hearing children. Frequently, it is not until the deaf child becomes an adolescent that increased opportunities to know other deaf persons arise, as well as opportunities to learn

ASL. A majority of deaf individuals are members first and continuously of one culture but are bilingual through ASL and English. Only in the past 30 years have deaf Americans vigorously established their identity as a deaf community. To characterize them as belonging to a major culture, that is, the American hearing society, is not as clear cut as it may appear.

Same Language, Different Cultures

There are many real-life examples of societies in which individuals may speak the same language but belong to different cultures. Although Brazilians speak Portuguese, they do not share the same culture as individuals living in Portugal. More than 35 million eastern coast and central Africans speak Swahili, but they belong to distinct nations and to tribes with distinct cultures. Even though Swahili may be the language of many people, residents of African nations speak other languages derived during European explorations, and many African languages intersect and cross nations.

Cultures are not limited to countries. In certain workplace cultures, such as those at the animation film company PIXAR or in regional and national orchestras, individuals may speak the language of that corporate culture. Members of legislative bodies try to speak the same language and interpret the language of their constituents to determine the passage of laws. In these instances, individuals belong to common workplace cultures but they may be separated from each other within their workplace by the cultures of families, friendship, or religions.

Language and Culture at the Lexical Level

We can learn much about the connection between language and culture by studying the availability and use of words in language communities. Edward Sapir comments that vocabulary is a very sensitive index of the culture of a people. Even at the lexical or vocabulary level, we can often get a sense of how individuals perceive themselves as members of society and members of specific cultures. The differences in word usage between languages can have serious implications for those who attempt to converse in a language not their own if they assume the same words in both languages carry equivalent meanings.

Freedom

In an analysis of the word *freedom* in five languages, Wierzecka shows that, not only does this word mean something distinct in each of the four languages, in some of them, some usages are not permitted. For example, in English, we can use *freedom* in contexts such as *freedom from* (interruption), *freedom to* (leave), *freedom of* (choice). In Polish, we define the word *wolność* in moral and political terms, a word we associate with oppression and matters of life and death. It is inappropriate to use it in phrases as we might in English, such as *freedom of access* or *freedom of movement*, or in sentences such as *A dog should be given its freedom*. We can, however, use *wolność* as we do in English when we say *freedom of conscience*.

Words by themselves do not have meanings; words take on meaning from individual use and as a function of the language and of the culture in which the words occur.

Language and Power in Culture and Society

In studies of ethnicity and race, researchers have recorded numerous instances of families and cultures considered *language minorities* but who insist that they will maintain the characteristics that define their people while living in a country outside of their country of origin. Fearing assimilation and loss of ethnic identity, migrants as well as ethnic and racial groups that may have resided in a country for years or even centuries may attempt keep their original languages and their cultures alive by developing isolated styles of living within the larger society. At times, the

choice to maintain cultural identity comes at the price of economic advancement, livelihood, and educational opportunity. Lambert and Taylor quote a Vietnamese adult living in Montreal: "I'm grateful to be here, but this is not my place of choice. I will not become less Vietnamese by living here."

In the United States, members of ethnic or racial communities who try to maintain their cultures and their native languages are sometimes able to resist assimilation. Although the distinct identities of many ethnic communities are dwindling, some, such as the Navajo nation, are growing—from 8,000 in the 1860s during the period of decimation by the U.S. government to more than 210,000 in the 21st century.

As we consider the power of language, we must recognize individuals' ability to adjust the use of language to more than one social context. Individuals who have few opportunities to interact outside of a small subgroup within a society can be victimized or placed in a role of subservience or isolation by those in the larger community who have a broader command of language. Conversely, because languages change as cultures develop, individuals with high degrees of competence in their mother tongues have the capability to support those who do not share that competence, expanding—as Lull terms it—the *dynamic ecology* of culture.

GLOBAL LANGUAGE

When Marshall McLuhan wrote his *Understanding Media* in 1964, he laid the foundation for what would emerge as a true "global village." What McLuhan might not have perceived at the time is that the language of that global village would be his own—English. The Internet that would bind that global village became known as the World Wide Web, a silicon-based communications system that brought together people from all over the world through the small screens of their personal computers. The origin of the Web can be traced to the work begun by the U.S. Defense Advanced Research Projects Agency (DARPA) in 1958, when the administration of President Dwight D. Eisenhower (perhaps the most unsung of computer pioneers) sought to develop a method of keeping alive the nation's communications grid in the event of a Soviet thermonuclear attack. Indeed, an early name for the Internet was the ARPANET. Yet it was not until 1975, 11 years after McLuhan published *Understanding Media*, that the first true personal computer, as opposed to the computers used by the government, universities,

and businesses, would appear. It was, as Ray Kurzweil wrote in *The Age of Spiritual Machines*, "the Altair 8800, which had 256 bytes of memory. A byte is a contraction for 'by eight.' A group of eight bits clustered together to store one unit of information on a computer. A byte may correspond, for example, to a letter of the English alphabet."

With the existence of the Internet and the beginning of the personal computer era that would make most homes and offices a part of it, there existed only the need for a communications medium to tie the two together. In 1990, Tim Berners-Lee at the CERN physics laboratory in Geneva, Switzerland, developed HyperText Markup Language (HTML). The development of HTML led to the conception of the World Wide Web. Before the Web, computer communications among individuals had been relegated basically to computer bulletin boards, a limited way of contacting others through the electronic ether. With the use of HTML, an explosion of computerized communication erupted with the full emergence of the Web in 1994.

From the onset, English appeared to be the language of choice on the new Internet. English already had a head start when, in 1994, America Online (AOL), the first Internet service provider, already boasted some 1 million paid members, who for a monthly fee could discuss everything from politics to their favorite sports teams or hobbies. Since then, English has preserved its dominance as the language of choice on the Internet. However, to make the Internet truly international, many Internet Web sites provide the ability for users to access the same pages in foreign languages as well. The most common languages after English are French, Spanish, Italian, and German, although there are sites in any language of the world as well. Some Web services also facilitate translations from English into other languages. Thus, by the 30th anniversary of the publication of *Understanding Media* in 1964, not only had McLuhan's global village come into being, but so had a common language to connect all its citizens—English.

VANISHING LANGUAGES

"A language is a flash of the human spirit," wrote anthropologist Wade Davis. Throughout history, perhaps 10,000 different languages have been spoken, but of the nearly 7,000 that still survive today, many are not being taught to children and fewer than half might continue to exist during this century. Some 450 tongues have only a few elderly speakers and are in immediate danger of extinction. Linguists estimate that one language dies every 2 weeks, taking with it unique ways of thinking, communicating, and living.

This linguistic impoverishment is considered a disaster that could threaten cultural diversity. As linguist Ken Hale argued, "Languages are more than grammar. They are cultures, ways of thinking about ourselves and our surroundings. When we lose one, it's like losing the Louvre." Linguists compare the disappearance of languages to the threat that the earth's biological diversity is facing from industrial pollution and population growth. This link is far from being simple rhetoric, and indigenous languages could play a role in environmental preservation because they often contain valuable ecological knowledge that enables speakers to preserve their habitats.

Among languages that have recently disappeared are Northern Pomo, a Californian Native American language; Sirenik Eskimo; Quinault, spoken by Native Americans in Washington State; Kasabe, spoken in the Adamawa province of Cameroon; and Ona, spoken in Tierra del Fuego in southern Argentina. Many languages have died out through human history, including those of major civilizations such as Sumerian, Assyrian, Babylonian, and Latin. Yet today's more technologically connected world is speeding up the process. English and a handful of other major languages that increasingly dominate the world are considered as linguistic passports to education and economic success. Spanish is killing native tongues in Latin America, and French is having a similar impact in its former African colonies. In southeastern Alaska, parents have stopped teaching native languages to their children.

The process of language vanishing has an economic base. When small linguistic communities

become economically impractical, they break up and the language dies out as its speakers relinquish it for the language of the larger community. For example, after Russia drove the roughly 50,000 Ubykh speakers from their homes on the Black Sea into Turkey during the 1860s, the Ubykh speakers eventually decided that the dominant Turkish, Abkhaz, or Circassian languages would be more useful. Over time, they stopped teaching their children their extremely difficult tongue.

LANGUAGE USE, SOCIOLOGY OF

Many disciplines in the social sciences and humanities systematically study language, each having its own theoretical foundations, goals, and research traditions. The resulting landscape is a maze of paths that start and then split off either to reemerge as hybrids combined with other specialties or to reach a dead end. For instance, psychology and anthropology joined with structural functional analysis to take a linguistic turn during the 1970s in the form of structuralism that, some believe, reached a dead end with poststructuralism. On the other hand, a team of 10 scholars (half linguists and half sociologists) spent 8 weeks of joint study at the 1964 Summer Linguistic Institute to purposefully give shape to a new field that was to be called sociolinguistics. Since that meeting, the number of publications, courses, and conferences that combine linguistic and sociological goals exploded and currently operates under the bifurcated categories of "sociolinguistics" and "sociology of language use."

Linguistic Universals Versus Variation

A major theoretical departure in the study of language pits linguistic universality against variation with its sociological counterpart found in theories of the relationship between influences of structure and agency. Within the former, the distinction can be traced to the work of Ferdinand de Saussure (1857–1913), a Swiss linguist whose main contributions were made through the published interpretations of former

students after his death. Saussure argued that languages are complete systems with two distinct layers: *langue* and *parole*. *Langue* is the consistent and complex template of a language that is possible due to the innate predisposition to knowledge of grammar that only humans possess. *Langue* is composed of systematic pairings of labels and their meanings called “signs.” A sign is the association between a signifier (label) and a signified (object or concept), and meaning is found in the relationship of signs to each other. Once acquired, the association between signified and signifier is taken for granted as being natural and irreversible.

Parole, on the other hand, is the historically and culturally variable manifestation of *langue*. At the level of *parole*, signs are relative and arbitrary. The association between signifier and signified is relative in the sense that *tree* and *arbre* are culturally distinct labels used to represent a similar concept. For Saussure, the substance and form of signs are also arbitrary. In other words, reality is divided and categorized differently in different cultures, resulting in variable linguistic forms. For instance, the language system of Inuits has far more signs for snow than do languages in climates where the distinctions are less critical. Representations that address such a fine array of differentiation allow people to reflect on and communicate important facets of their culture. Conversely, a lack of representation precludes reflection or communication of concepts that have not been linguistically noted in a culture. For Saussure, by the time individuals reach maturity, a complete *langue* has been acquired and it becomes nearly impossible to separate the signifier from the signified (i.e., the label from the concept). Consequently, words and thoughts become one. Although originally created at the level of *parole*, once language is established, it becomes autonomous and the autonomy of the subject is undermined or lost entirely.

Noam Chomsky, a student of Saussure, reframed the *langue/parole* duality into that of competence and performance, placing priority on the universality of competence. Chomsky asserted that the human brain allows language, and he described how the brain is organized through the study of language structure. According to Chomsky, children are born with an innate mental propensity to understand grammar. Competence, referring to the unfolding of the innate knowledge of language structure, is the only way to account for children’s ability to use the wide range of grammatical variables found in language without

consciously being aware of the complicated rules and exceptions that govern its structure. Performance is learned through social action and is merely the surface structure of a particular linguistic code that is driven by the deeper structure that lies beneath all language systems. Although he later changed his focus, Chomsky believed that discoveries about linguistic universals, which he termed “generative” grammars, were more interesting and had more promising explanatory potential than did performance. The task of linguists was to reveal the underlying structures to be found in all languages by writing grammars that would develop an understanding of language as a system and, from that, provide insight into the human mind and social structure.

Claude Lévi-Strauss, a structural anthropologist who was influenced by Saussure and Sigmund Freud, stressed the invariance of human nature caused by a biochemistry of the brain linking the social activities of societies across cultures and history. He analyzed myths (i.e., the stories that people tell about themselves) in terms of the relationships between phrases to uncover the latent structure of society. This form of structuralism is based on the view that studying relationships among signs reveals more about the human condition than does analyzing the use of language. For structuralists, discoveries of universals can be drawn from observations of anyone and, therefore, no one in particular. They also must rely on observable, but superficial or secondary, occurrences to explain underlying and primary structures.

Poststructuralists reversed the structuralist pursuit of material structures through the study of language to an orientation toward the deconstruction of discourse to see how it operates below the level of intention and consciousness. There are several definitions associated with discourse analysis. For one, it refers to a type of analysis that highlights the rules and dynamics of speech and conversation in relation to the social situation. Discourse also refers to the production of ideology, in other words, the function of language to create a version of reality in favor of the ruling class. Finally, discourse also refers to a line of inquiry that assumes no objective reality outside that which is manipulated through language.

From an extreme development of logic found in poststructuralist discourse analysis, there is no external reality outside that created by language. Because language structures are universal rather than personal, human presence is uncovered only through

an examination of a subjectless text. Michel Foucault (1926–1984), perhaps the most notable poststructuralist, aimed at establishing the origins and changes in meaning structures over time. From both structuralist and poststructuralist points of view, social actors are “decentered” to a position of being mere products of discourse whether originating from innate structures or from historical developments in language. Critics such as Anthony Giddens have noted that the death of the subject and of objective reality brought about the death of this line of reasoning. However, other less extreme forms of discourse analysis remain legitimate lines of inquiry into language use.

Sociolinguistics and Structural Functional Variation

Both the linguists and the sociologists who met to combine their disciplines to shape sociolinguistics during the 1960s rejected approaches that lacked concern for correlations between social structures and the variability in the individual use of language. Although they share an interest in linguistic variation and its association with social reality, sociolinguistics from a linguistic approach attempts to discover linguistic structures within a social context, whereas sociolinguistics from a sociological approach attempts to discover social structures by studying actors using language. At its onset, however, sociolinguistics took on a predominantly structural functionalist point of view. This was the case for sociologists because Parsonian theory was at its pinnacle during this time, and it was the case for linguists because it was their tradition.

The structural functionalist approach to social structure is quite different from that of the structuralists. For the structuralists, structures are the underlying principles on which social patterns are built. On the other hand, structural functionalism refers to structure as the observable patterns of social practices such as roles, norms, and language that have been intentionally or unintentionally created or reproduced by social actors. Following this definition, sociolinguists view language as, first and foremost, a social and cultural product, and linguistic variation must be studied in social context. It emphasizes a social order that derives from normative consensus, with the individual operating in line with specific social constraints that derive from this social agreement.

A central premise of sociolinguistics is that language is social in the sense that it is a mirror of society. Speakers use language varieties that reflect their differences in terms of regional, social, and ethnic statuses. Social variables such as style (degree of formality within a social context), social characteristics (class, race/ethnicity, gender, and age), social structure (norms and roles), and social status (ranking) are independent variables to the dependent linguistic variables. Therefore, sociolinguistics relies heavily on hypotheses that correlate social characteristics as independent variables with dependent linguistic variables.

Linguistic units that vary within differing social circumstances form a continuum composed of deviations from a standard or proper form and can be observed occurring more or less frequently. Inquiry focuses on the social determinants of the selection of linguistic variants in accent and dialect emphasizing phonemes, morphemes, phrases, and clauses that are considered to be variant, continuous, and quantitative. Much of this research prioritizes empirical matters over theoretical ones.

In 1958, a sociologist, John L. Fisher, was one of the first to conduct research that correlated social characteristics with linguistic variables. He found variations in the use of the suffix *-ing* (pronounced either [ing] or [in] such as in running or runnin') among the speech patterns of children in New England. He found that the less standard form [in] was used more frequently by boys than by girls, by working-class children than by middle-class children, and in a casual context than in a formal social context.

Studies by sociolinguists such as William Labov and Peter Trudgill provided seminal insight into how language represents social organization. The later work of the linguist Labov is usually regarded as the model for quantitative studies of variation. In early studies, he observed the social context in which the postvocalic *r* (i.e., *r* pronunciations after vowels) occurred in New York speech patterns. His independent variables were social class and style. He found that the postvocalic *r* was pronounced most often by upper middle-class speakers and was dropped most often by New Yorkers observed in casual social settings rather than formal ones. He also found that women of lower middle-class status used a greater range of variability than did working-class or upper middle-class women. In other words, lower middle-class women dropped the *r* much more often (in fact,

they practically never pronounced the postvocalic *r* in casual conversation but did pronounce it significantly more often than upper middle-class and working-class women when speaking in more formal social circumstances. Labov hypothesized that lower middle-class women were more conscious of social mobility and, therefore, were more willing and able to change their language to adapt to social circumstances that required a more standard or prestigious variation. He called this process “hypercorrection.”

In 1974, Trudgill explored sex and social class as determinants for using 16 phonological variables in a study conducted in Norwich, England. Extending Fisher’s work with children, Trudgill found that working-class males used the less standard form of *-ing* (for example, *singin’*) much more frequently than did working-class females. He concluded, and others since have consistently concluded, that women are more likely than men to use standard forms of language and also to have access to a greater repertoire of linguistic variations. A common explanation is that women are more status conscious and less secure than men and, therefore, use a more prestigious form of language. Another explanation is that women are more likely than men to use an interpersonal strategy called “face” to maintain self-esteem in social exchanges. A feminist critique is that these explanations conceptualize female linguistic strategies as deviant from the standardized or more normal male strategy.

A Sociological Approach

In 1992, Glyn Williams contended that sociolinguistics was far more influenced by linguistic goals than by sociological goals at its inception during the 1960s and remained that way. As evidence of this, many more linguistics departments include courses in sociolinguistics than do sociology departments. A main sociological critique of sociolinguistics is that its purpose is not to learn more about a particular society, or even to examine correlations between linguistic and social phenomena, but rather to learn more about language and to investigate linguistic change, variability, and the structure of languages. Also, its heavy reliance on consensus theory limits alternative theoretical perspectives and methods. Although sociolinguistics emphasizes empirical positivism and theory building, it is void in theoretical critique.

A subdiscipline within sociology that focuses on language must use an approach that relies on its

disciplinary foundations. Critics deny the legitimacy of a specialty called the sociology of language use, suggesting that it still lacks a dominant or integrated theoretical basis that could progress to specific hypotheses and the collection of data that could be analyzed to test the originating theory. Nonetheless, the sociological interest in language expands the gamut of sociological thought. It includes analysis of the negotiation of meaning in conversation, of questions about the construction of reality, of its importance in the process of socialization and identity formation, and of the role of language in social inequality and oppression.

Although sociology at the macro level is often concerned with social systems that, as a whole, are greater than the sums of their parts, it is also the study of social life and behavior at the micro level along with the connection between the two. Like all fields in sociology, the sociology of language use must combine interest in social systems (how they work, evolve, and affect individual lives) and individual behavior (how individuals participate in creating, reproducing, and changing social systems).

An introduction of agency into explanations of society is found in the theory of Georg Simmel (1858–1918), a German sociologist who opposed a structuralist view of social behavior. He viewed society as “a collection of people connected by their interaction with one another.” For Simmel, structure exists only through the constant achievement of individuals involved in interaction. Interactionist theories derived from Simmel view social systems largely as abstractions that have no existence independent of what individuals actually do in relation to one another.

Ethnomethodology is an approach within the framework of interaction theory that examines how human agency and the use of language affect perceptions of social reality. It emerged simultaneously with structuralism, but in direct opposition to it. Ethnomethodologists locate structure not in language systems but rather in the ways in which actors use language to create and maintain an ongoing sense of reality. As originated by Harold Garfinkel, it is the study of the methods that people use in everyday interactions, emphasizing the ability of individuals to create social situations. To gather data, ethnomethodologists use conversation analysis, where interactions in everyday natural settings are audio- or videotaped to systematically capture, code, and analyze the methods used by individuals to create social reality.

Critics point to the way in which ethnomethodology reduces social behavior to the rational behavior of social agents and how it cannot account for regularities other than those that arise unintentionally from purely individualized behavior.

Symbolic interactionism provides a theoretical foundation that brings more balance to the micro–macro paradox of causality. Individuals are seen as the core of social life, providing social systems with their fundamental form and creating reality through negotiated interaction. Symbolic interactionists study how symbols such as language are adopted and exchanged through mutual interpretation not merely to communicate but also to create and maintain a self-identity (internal) and impressions of ourselves (external) and to create and sustain our experience of particular social situations. Although shared meanings create a type of structure, structures are always emergent, fluid, and ambiguous. Language becomes the link between individual agency and social structure.

The anthropologist Edward Sapir (1884–1939) and his student, Benjamin Lee Whorf (1897–1941), developed a theory that has become known as the Sapir–Whorf Hypothesis and serves as the linguistic equivalent to this connection between structure and agency. It considers the bidirectional connection between linguistic variation and universality. The main tenet is that language not only expresses our ideas about social reality but also shapes these ideas. The theory has two parts: linguistic relativity and linguistic determinism. Linguistic relativity corresponds to Saussure’s theory of the arbitrary nature of signs and infers no absolute or natural way to label objects, ideas, or experiences. Each culture divides up the world differently, and a particular perception of the world influences the language that is created; therefore, language represents perception. Linguistic determinism states that language is also the framework for our thoughts and perceptions. The most useful implication from the Sapir–Whorf hypothesis is that the reciprocal or nonrecursive relationship between social structure and agency avoids the extremes of both determinism and relativism. Language enables us to create reality by substituting words for direct experience. It is central to culture because it is through language that we are able to create and transmit culturally shared meanings of human experience, thought, feeling, and behavior. Sociologists, in particular, believe that variation in the

ways in which language is created and used and the impact that variation has on differential perceptions of reality is at least as interesting as, and perhaps a more fruitful endeavor than, models limited by structural functional theory.

Basil Bernstein studied language as a bidirectional relationship between structure and agency through the process of socialization. Openly influenced by the Sapir–Whorf Hypothesis, Bernstein regarded language as something that both influences culture and is in turn influenced by it. He noted the distinctions in language use associated with socioeconomic standing, particularly the link between language acquisition and social reproduction. His interest in language extended to a general interest in how class systems are maintained by having control over knowledge and the language needed to access and use it in complex and creative ways. His basic premise was that social location has a linguistic environment that is learned through socialization from generation to generation and that, reciprocally, one’s acquired language influences social standing. In his theory of speech codes, Bernstein argued that social class affects how students learn language in their family and school environments and that this, in turn, affects their achievement potential and social class possibilities.

Specifically, Bernstein found that people in the working class use a “restricted code,” whereas those in the middle class have additional access to a more formal or “elaborated code.” The elaborated code makes use of standard grammatical order and syntax and uses complex sentence structures that employ devices for conjunction and subordination clauses and prepositions to show relationships of both a temporal and logical nature. This variation also exhibits the frequent use of “I,” a wide range of adjectives and adverbs, and qualifiers that he believed are conducive to expressing complex conceptions of experience. On the other hand, the restricted code employs short, grammatically simple, and often fragmented sentences of nonstandard form; uses few conjunctions or subordinate clauses; uses a limited variety of adjectives and adverbs; makes infrequent use of the pronoun “I”; and makes frequent use of idioms. According to Bernstein, everyone has access to this variety, which is used on occasions of familiarity. However, working-class families do not have access to the more formal and complex elaborated code due to their lack of experience in using it.

A controversial interpretation of Bernstein’s theory is that socioeconomic groups that are limited to using

a restricted code are at an essential disadvantage, rather than a social disadvantage, when communicating in establishments such as educational systems and occupational organizations that favor an elaborated code. Although the codes have different characteristics and social consequences, Bernstein refuted that his theory implies differences in practical utility.

Pierre Bourdieu, on the other hand, made a utilitarian distinction in the acquisition of language. Bourdieu was a French sociologist whose general theory bridged the gap between individuals and social structures by examining the link between education and culture. He discussed language use in terms of the variation learned during an individual's early years as a form of cultural capital that acts as a condition for the reproduction of social order. For Bourdieu, language is part of a person's *habitus*, which is the totality of cultural aspects acquired during early stages of socialization. Cultural disadvantage is proportional to the distance between one's *habitus* and that of mainstream or dominant culture. A child who has acquired a vernacular that deviates far from the standard, such as in minority student populations, has less cultural capital to spend than does a child who has learned a more standard variety. The minority child will experience symbolic violence in social situations where standard language is used. For the minority child, academic goals are harder to reach because the ideas and concepts to be learned are delivered in an unfamiliar and, therefore, hard to understand linguistic variation.

Another major thread in sociology, originating with the work of Karl Marx and Frederick Engels and informing the study of language, exalts social theory critical of oppression and domination. An understanding of ideology as the meanings created by the dominant class to self-preserve their social status has been the center of most studies of language among contemporary Marxists, leading to what is referred to as critical sociolinguistics. French sociologists have been particularly prominent in the theoretical reevaluation of the role of language in ideology. Foremost among such critics is Foucault, whose basic argument is that language and knowledge form a basis for power in their roles in the social construction of reality. Content analysis of political and media rhetoric in the construction of ideology falls under this category of analysis. Language as a link between individuals and their social and cultural locations makes it a legitimate field that can address a wide range of sociological theory.

Sociolinguists often criticize the sociological study of language use, even including the work Bernstein to whom the origination of the sociology of language use is usually attributed, on the grounds that it has "no linguistic objective." Sociologists have a greater concern for the empirically rigorous but limited usefulness of sociolinguistics that emphasizes formal linguistic theory rather than social theory. More important, adherents to the sociology of language use wishing to advance the field must systematically address the difficulties inherent in applying empirical research designs to its rich theoretical heritage.

Work in animal behavior, and in particular cognitive ethology, has shown that most of the differences in kind once thought to distinguish humans from other animals are actually differences in degree. The one behavior where a huge gap still seems to exist is language.

Language is best defined as a communication system that employs arbitrary signals to refer to things distant in time or space. It is not simply a way of advertising a creature's species and sex—the role of the vast majority of animal communication. Thus, the flashing of fireflies, olfactory signaling of moths, croaking of frogs, and mate attraction calls of birds are specific here-and-now signals; they are no more a matter of language than are body shapes or the movements involved in locomotion.

One scenario for the evolution of language is that it developed from preexisting systems of animal communication. This hypothesis suggests that the previous communication systems would have needed multiple signals to give evolution a start. In social animals, including animals that are social only during reproduction and the rearing of young, there are generally many innate calls or other signals that permit the necessary coordination of effort. Monogamous birds, for instance, have approximately two dozen unique calls used during pairing, incubation, and feeding of nestlings. Social primates have roughly the same number.

True language is found in two highly social species: honeybees and humans. In bees, the foragers communicate to potential recruits the direction, distance, and quality of a food source; the language is also used for pollen, water, and nesting sites. In two species, the dances occur on vertical surfaces in the darkness of the hive, out of sight of the food (up to several thousand meters away) and minutes or even hours after visiting the site.

The arbitrary conventions involve taking vertical in the hive to correspond to the direction of the sun and considering each “waggle” and sound burst in the dance to correspond to a specific distance flown. “Up” could just as easily have been referenced to the direction the hive faces or to the north; at least these directions do not change with time and would not have required the elaborate time compensation system by which the dance angle is changed to reflect the unseen motion of the sun outside. The arbitrariness of the distance convention is particularly clear; different subspecies of honeybees have different waggle-to-meters dialects.

Impressive as it is, the honeybee language is both wholly innate and closed; that is, no new arbitrary conventions (words or grammar) can be added to the system. At the same time, we now know that human language depends on enormous amounts of inborn help; consonants are innately recognized,

vowel categories are innately sorted (although culturally defined), specific brain areas (generally on a particular side) are present from birth, a default word-order grammar is in place, a “deep structure” for encoding and decoding is built in, and strong drives exist to categorize, learn grammatical rules, and acquire a vocabulary.

Perhaps the wealth of innate circuitry should not have been a surprise. Language is, after all, a species-specific human behavior that develops in all normal children at a characteristic age independent of active teaching or error correction. On the other hand, the intellectually trivial skill of multiplication is never learned spontaneously and always requires error correction.

Comparing humans with primates, the obvious candidate for the initial components of language is the set of innate calls, which could correspond to consonants. In certain species such as vervet monkeys, some of these calls have highly specific meanings such as a predatory bird, snake, or leopard in ambush. Like most human language, these calls are “inflected”; that is, alteration of the beginning, duration, or ending add meaning to the signal. The right-angle bend from spine to head engendered by walking erect created the two separate chambers necessary to produce vowels and, thus, created a huge number of syllables when combined with approximately three dozen consonants. But how this potential was turned into the elaborate mix of innate and acquired features that is human language remains a mystery.

LANGUAGE, CLASSIFICATION OF

To classify the languages of the world, it is of foremost importance to first decide what constitutes a “language.” Most classification schemata involve spoken

languages—alive, endangered, and extinct. The estimated number of spoken languages varies from 3,000 to 10,000, and there are languages spoken by a few societies that are still unidentified. There are some languages that have different names in different cultures, and there are some that have no names. There are languages that are classified as “major” because they are used by numerically large populations of people (for example, English, Polish). There are languages that are used between and among many societies as contact languages besides their individual native or national languages. Sometimes a society will use the term *dialect* synonymously with *language*, and sometimes a name is used to refer to a language group as well as to a single language. If one takes into account that some languages have writing systems or can be identified only historically as written forms, and that some languages have sign forms or are strictly sign languages, the method of classification becomes even more complicated.

Families, Branches, and Languages

One systematic approach to language classification separates spoken languages into “families” by tracing each language to its possible origin or the geographic place(s) where it was historically documented to have branched off of a parent language. The family system of classification began with philologists theorizing and grouping languages first into the Indo-European family. It is believed that the languages in this group

are derived from a parent language, “Proto-Indo-European,” that may have been spoken before 3000 BCE. As indicated in the name, the languages in this family were generated throughout Europe and parts of southern Asia. The Indo-European language family branches off into superordinate categories (for example, Germanic), to subordinate categories (for example, East Germanic, West Germanic, North Germanic), and finally to languages (for example, English, Dutch).

In 1997, David Crystal listed 29 world language families in the *Cambridge Encyclopedia of Language* as well as languages that are termed “isolates” because linguistic analyses of these languages do not show features that are common in any specific schema of the existing families (for example, Basque, Australian Aboriginal).

Criteria for Language Classification

Early philologists and historical linguists of the 18th and 19th centuries explored the similarities and differences between specific target linguistic structures in particular spoken languages and subsequently tried to determine the possible ways in which the languages developed. These early researchers provided a basis for their successors to create language classification systems. The objects of special interest in comparative linguistics are phonology, morphology and words, and syntax.

Purposes for Classification

Scholars have attempted to classify languages with particular purposes in mind. The first purpose is to have a record of all the world’s languages, but there are other reasons for classification. One of these purposes is for the demonstration of cultural and cross-cultural patterns given that native languages and commonly spoken languages have previously been classified linguistically.

In 1997, Philip Parker provided a detailed statistical analysis of more than 460 language groups in 234 countries to illustrate issues connecting linguistic cultures to nine areas of concern (such as economics, cultural resources, demography) with key variables for each area (railways, water, telecommunications). His analyses are especially valuable for the development of

nations, especially those designated as Third World countries.

Along a similar vein, scholars have attempted to classify languages according to their use between and among cultures and across nations. Such an endeavor is particularly challenging because there are historic dimensions as well as current cross-cultural variables that need to be characterized in the documentation.

Language Change and Extinction

Another reason for classifying languages is to understand language change, the extinction of languages, and the rebirth of languages. Stephen Wurm and Ian Heyward produced two successive editions of an atlas that identifies world languages that are endangered to greater and lesser degrees as well as those that are at the brink of extinction. At the beginning of the 21st century, researchers around the world consider the situation of language death to be an especially serious one. In Papua New Guinea, for example, there are approximately 820 local languages, and the national language is a Creole, Tok Pisin. Although the government has a positive attitude toward language diversity in New Guinea, by 2001 there were 75 languages in threatening circumstances and 16 extinct languages.

Reasons for concern regarding language extinction include the influence of dominating or dominant languages that cause adaptations to minority languages. In places where trade occurs with major nations of the world, native language speakers may adopt and adapt their own languages to accommodate communication. Currently around the world, there are Creole languages that have become the vernaculars of a number of language communities, and this has been at the expense of previously existing languages.

The Persistence of Spoken Languages

Although there is much concern regarding looking for trends in the endangerment and extinction of languages, there is a hopeful side to classification as well. Certainly, researchers must be pleased when they can take a language off the endangered list or when they can see language growth.

In Togo, a tonal language, Ewe, is one of two indigenous languages that are spoken by more than 4 million people there and in adjoining Ghana. It is a primary language for use in the government, in education, and in mass media. Ewe also has a written

form, and there is a body of literature written in Ewe. Togo has a commission to devise Ewe words for technological terms. Felix Ameka recently explained that Ewe is very important for life in West Africa but that the population is in regular contact with English, French, and other indigenous languages in the region. Yet it appears that the people's efforts to stabilize the identity and use of Ewe are showing results.

LANGUAGE, ORIGIN OF

Language represents a fundamental character of modern humans, *Homo sapiens*. All animals engage in some form of communication. For example, single-cell organisms may relate to individuals around them via chemicals, whereas birds prefer more vocal communication. Researchers who study communication in nonhuman animals, such as Sue Savage-Rumbaugh (in bonobos) and Irene Pepperberg (in parrots), may argue that human communication skills are not very different from those of some animals. However, researchers continue to debate the question of whether any species other than humans are capable of language, although there does appear to be a significant difference between animal communication and human language. Human language evolved over the course of several million years through the modification

of the hands, larynx, and brain, arising as an elaborate form of gestural communication in the ancestor of apes and humans to become the vocal communication observed throughout cultures today.

What Is Language?

Communication, which all forms of life engage in at some level, can be thought of as a process in which information is exchanged between individuals through a system of symbols, signs, and/or behaviors. This could include the use of odors that can determine rank, sexual status, location, and a host of other information forms of which humans have little understanding. Nonhuman primates make use of odors to express and convey some information, and humans do this as well to a certain degree. Where primates differ dramatically from other animal groups is in the use of gestures for communication. Gestural communication includes everything from the obvious, such as a sweeping hand or body motion, to the subtle, such as a slightly raised eyebrow.

Excellent examples of communication abound in nonhuman primates. For example, gelada baboons (*Theropithecus gelada*) live in the mountainous region of Ethiopia. The uneven terrain of their habitat makes it impossible for individuals in separate groups to communicate with each other using the vocal calls familiar to other primates and especially birds. Geladas use primarily gestures to communicate to distant groups often positioned at varying elevations. When the male of a group wants to send a warning to a male in an adjacent group, the first signal that he may give is a wide yawn that exposes his large canines. This somewhat benign gesture indicates to the other male that he is a little too close for comfort. If the adversary does not respond appropriately, he may receive a brief look from the male in which the eyebrows are briefly raised to reveal a patch of white skin around the otherwise dark skin eyelids. This gesture makes the eyes appear larger than normal and makes the other male understand that he is being watched closely. The gelada may engage in a variety of long-distance gestures that culminate in an eyebrow raise with a lip-flip accompanied by a sharp thrust of the body and face in the direction of the antagonist. This lets his adversary know that the next gesture may be actual physical contact, the ultimate gesture that most organisms avoid if possible.

Geladas, however, do not focus all of their gestures on aggression. They also use them to communicate sexual status. Geladas spend more time sitting than do other baboons and, as such, do not communicate sexual status to each other in the same way as is seen in other nonhuman primates. In most species of primates, females develop obvious swellings of the external genitalia around the time of ovulation. These swellings are an indicator or form of communication to males that a mating at the time of maximal swelling has a better chance of being successful. Geladas, however, do not produce swellings that are as obvious as those of other baboons. Instead, geladas possess a hairless patch of skin on the chest that changes color and develops nodules as the female enters into estrous. Moreover, like other primates, the female will solicit the male around the time of estrous to indicate that she is willing to mate with him.

Geladas do not engage in the most elaborate forms of communication known in nonhuman primates, but they do provide an excellent example of how communication works in nonhuman primates. Most forms of nonhuman communication are restrictive and stereotypical. All male geladas use eyebrow raises, yawns, and lip-flips to communicate threats to other males, and the order in which the gestures appear is predictable. Vocal communication is no different. Primates and birds are capable of producing a vast number of sounds, yet they only use a limited range of vocal calls to communicate.

Based on the results of studies on nonhuman primate as well as those on other animals, it is obvious that communication and language are not the same. Language involves a systematic method of communicating that incorporates gestures, sounds, and signs that have understood meanings. In addition, language takes the elements of communication and places them into a system that allows the speaker to alter the way in which the elements are presented to convey a different thought by adhering to the rules of the language. Known as syntax, the rules of a language determine the order of words in a sentence, enabling the speaker to convey an infinite number of ideas so long as they are presented in the correct sequence. For example, the sentence "This is the house that Jack built" makes it known to the reader that Jack built the house the observer sees. However, the sentence "Jack is house this built that the" may have the same words as the preceding sentence but does not convey the same thought and is perceived to be nonsensical because

the presentation of the words does not adhere to the syntax of the language.

Language also differs from gestural communication in that it allows the speaker to express ideas that concern the past or future. In general, communication is literal and is concerned primarily with the present. Although a male baboon may be able to present a gesture that tells the receiver that he should move away from the group or else he may be attacked, the gesture does not indicate that the receiver should move away or else he will be attacked tomorrow. Indeed, even human gestures indicate nothing of future or past events unless they are presented in the context of a formalized language such as sign language (for example, American Sign Language) or gesturing while talking.

Although primates, especially chimpanzees and bonobos, are capable of incredible feats of communication, such as learning sign language or a set of symbols that carry meaning, they do not engage in language as defined in humans. Moreover, they do not develop languages on their own, a trait seen in humans. However, this does not imply that the apes are not unique among nonhuman primates for the elaborate nature of their communication. For example, Kanzi, a bonobo, understands more than 200 symbols and has developed the ability to string symbols together into phrases that enable him to convey a thought or understand a command. This does not indicate that chimpanzees possess a language or are capable of language given that Kanzi's ability for language is little better than that of a 2½-year-old human. Nevertheless, Kanzi's capacity to learn elements of language indicates that the seeds of language extend back beyond the evolution of modern humans.

The Requirements for Language and Speech Production

Language has evolved through the adaptation of three structures to accommodate the requirements of verbal and written language: the brain, larynx, and hand. Without changes in all three from the ape condition, it would not be possible to place words into a structured syntax. Moreover, it would not be possible to understand what the words on this page mean without changes in the brain other than those required to produce language.

The Hand

The hand is an often-overlooked aspect of language. The hands (as well as the whole body) are used for gesturing, which at its most basic level conveys a simple thought much as gestures in nonhuman primates work. However, hands also play an important part in language. During conversation, the hands as well as the body can be used to emphasize the point of a sentence or the action contained within it. The dexterity of the human hand allows people to produce an infinite variety of gestures that can be used to make language more efficient. For example, a person can efficiently explain how much smaller one object is than another object by using his or her hands while speaking rather than spending time using words to explain the difference.

The hand is also important to written language. Without the manual dexterity exhibited in the human hand, it would be impossible to manipulate the fine movements of a writing instrument on a page. This ability is the product of significant changes that occurred in the muscles of the thumb.

In chimpanzees and other primates, the muscle that flexes the tip of the thumb is the same as the muscle that flexes the tips of the other four digits, the flexor digitorum profundus. Although chimpanzees share the other muscles of the hand with humans, the lack of independent control of the tip of the thumb prevents nonhuman primates from manipulating objects in the same manner that is seen in humans. In humans, the thumb or pollex has a tendon with an independent muscle belly running to the tip of the thumb, the flexor pollicis longus. This muscle enables the thumb to strongly oppose the other digits. It gives humans the ability to hold a hammer firmly through what is called a power grip. It also lets humans hold a piece of paper firmly between two digits in what is referred to as a precision grip.

The origin of the flexor pollicis longus, and thus the power precision grip, occurred approximately 2.5 million years ago when tool use appeared, according to the human fossil record, with the first members of the genus *Homo*. Humans from before this period, like chimpanzees today, used tools, but these were relatively simple tools that required little modification such as digging sticks. Stone tools represent an essential shift away from the lifestyle of the first hominids and apes to one that resembles that of modern traditional cultures.

To manufacture a stone tool, one must have the ability to form a mental picture of the finished

product, which has no resemblance to the original stone. A stone tool is derived from a core stone. To form a tool, the core stone is hit with a hammer stone to remove flakes, which can then be modified to create the tool or be discarded if the core stone is to be modified into a tool. To remove flakes from the core stone, it is necessary to hit the core stone in the correct location. These precision blows arise from the power precision grip and eye–hand coordination.

Although tool use is not language, many researchers, such as Ralph Holloway and William Calvin, believe that the expansion and reorganization of the brain, and thus the rudiments of language and its evolution, may have begun with tool use. This is in part because once tool use develops, humans begin to move away from the social nuances of their ancestors and more toward groups involved with cooperative gathering and scavenging and later hunting. Such cooperative living would have encouraged the development of more complex forms of communication. Also, once languages developed, the dexterity of the hand allowed for the development of a written language. Although the first formal written languages are only a little more than 5,000 years old, it is possible that informal written languages date back beyond 30,000 years through the use of drawings and other ornamentation.

The Larynx

Speech is the most recognizable aspect of modern human language. Humans have an ability to produce an infinite variety of sounds that can be strung together to form words. Although the possibility of human-like communication skills in other species is debated, the uniqueness of human speech is not. Only birds have the ability to approximate human speech, yet no single species of bird is capable of producing the entire range of sounds in the human repertoire.

Human speech is the product of modification of airflow from the lungs by the larynx and the supralaryngeal airways (for example, pharynx, nasal cavity, oral cavity, mouth). Although none of the features is unique to humans, the arrangement of the structures permits a speaker to produce the subtle sounds associated with any language. Of these features, however, the larynx appears to have undergone the greatest change.

Study by researchers such as Edmund Crelin, Jeffrey Laitman, and Philip Lieberman on the hominid larynx has revealed that the position of the human larynx is most responsible for the range of sounds associated

with human speech. All nonhuman primates have a larynx that is positioned high in the throat, a condition found in most mammals. The normal mammalian condition allows the larynx to overlap the soft palate. This gives mammals the ability to drink and breathe at the same time because the high position of the larynx lets liquids flow around it and into the esophagus without crossing the path that airflow follows. This condition likely evolved to let prey animals flee predators more effectively when drinking at exposed watering holes. The drawback to the normal mammalian condition is that nonhuman mammals lack the ability to produce the range of sounds of which humans are capable.

In modern humans, the larynx sits low in the throat. The low position of the larynx creates an additional space in the supralaryngeal airway called the oropharynx. This added space, in addition to the extra distance air travels before it reaches the lips, allows humans to produce additional sounds that other mammals cannot produce. Indeed, even birds lack the ability to produce the range of sounds that adult humans can produce. Much of the ability of birds such as parrots to form sounds that mimic those of human speech patterns are perceived rather than the result of true mimicry.

Not all modern humans, however, produce the same range of sounds. For example, an infant is incapable of producing little more than a few sounds that may carry meaning but are indecipherable to an adult. This is because the larynx at birth is in the normal mammalian position. It is not until the child is around a year old that the larynx begins to make its descent into the throat. This descent can be observed in any child as he or she progresses from making baby talk to producing sounds more consistent with human speech. By the time an individual reaches the final stages of puberty, the final changes in the larynx and related structures are complete.

The position of the larynx in the throat in primates appears to be related to the degree of basicranial flexion observed. In chimpanzees as with other mammals, the base of the skull is flat in profile, whereas that in adult modern humans is flexed toward the anterior side of the midline. The degree of flexion in the skull base relates to the degree of laryngeal descent. With a flat skull base, a chimpanzee has a larynx that sits high in the throat. Because of this position, chimpanzees are unable to produce a variety of vowels and consonants that adult humans use. When one looks at

the hominid fossil record, it is apparent that the descent of the larynx is a relatively recent phenomenon.

In early hominid fossils such as *Australopithecus afarensis* at 3.5 million years ago, and likely back to *Australopithecus anamensis* (4.2–3.9 million years ago) and even *Sahelanthropus tchadensis* (7.0–6.0 million years ago), the skull base resembles that of a modern chimpanzee. In fact, nearly the entire morphology of the face is more reminiscent of an African ape than of a modern human. This morphology indicates that the larynx would have resided high in the throat, meaning that early hominids would have been incapable of modern human speech. Instead, they would have been limited to the range of sounds seen in chimpanzees.

Later in hominid evolution, the cranium began to shift away from the ape condition of a prognathic or jutting face, small brain, and flat cranial base to a more vertical face, large brain, and flexed cranial base. Although the appearances of these features do not coincide with each other, the gradual shift toward the condition seen in modern humans implies that speech capabilities evolved gradually over time. The first indication of a possible change in the position of the larynx occurs in *Homo erectus* (also called *Homo ergaster* for early members of the species from Africa). The skull base of *H. erectus* (1.8–0.4 million years ago) is only slightly flexed over the condition seen in earlier hominids, but the slight flexion of the cranial base may indicate that *H. erectus* was capable of producing a greater range of sounds than *A. afarensis* would have been able to produce.

With the appearance of *Homo heidelbergensis* (400,000–150,000 years ago), the skull base becomes more flexed. Again as with *H. erectus*, *H. heidelbergensis* was likely incapable of producing the range of sounds seen in modern humans. Neandertals, once considered a subspecies of modern humans, have a skull base similar to that of *H. heidelbergensis*. Although they possessed cultural characters more similar to modern humans than did previous groups of hominids, it is likely that even Neandertals were limited in their speech capabilities.

It was not until the appearance of *H. sapiens* some 200,000 years ago that modern human speech capabilities arose. Modern humans are the only hominid group that possesses marked skull base flexion. Cranial base flexion allows the larynx to reside lower in the throat, adding to the distance a sound travels before it passes out of the mouth. With this morphology,

humans have the ability to manipulate a puff of air coming from the lungs to form difficult sounds such as “b” and “p” in addition to the various forms of each consonant and vowel found in different languages.

The Brain

No other structure in human evolution receives more attention than the brain. The human brain is capable of things well beyond the abilities of any other creature. Arguably the most unique ability of the human brain is its capacity for language. With language, humans are able to communicate ideas beyond the simple emotions conveyed through the gestural–visual communication of the great apes. However, although the mental capabilities of modern humans are apparent and easy to assess, those of the fossil ancestors of humans are very difficult to define. Despite this shortcoming of the fossil record, it is possible to understand what is required for language in the brain and when those features may have developed in human evolution.

In 1861, the eminent French physician and anthropologist Paul Broca described what he called the “seat” of language in the brain. By studying a patient who had suffered damage to the left frontal region, Broca found that although the patient developed the ability to understand speech during the course of therapy, the patient lacked the ability to produce language except in limited capacity. Over time, the region associated with language production, which would come to be known as Broca’s area, would be isolated to the inferior third convolution (gyrus) of the frontal lobe.

Broca’s area represents the motor speech area of the brain. Located in the left inferior frontal lobe in most right-handed and some left-handed people, this region allows the intricate muscle movements of the lungs, larynx, and supralaryngeal airway needed for modern human speech production. Moreover, this area allows the fine movements of the hand required for writing. As Broca discovered, damage to this region of the brain may leave a person incapable of communicating with others.

In 1874, the German neurologist Carl Wernicke completed the language picture by identifying the area of the brain for language comprehension. Located posterior to Broca’s area in a region called the parieto–temporal junction, Wernicke’s area enables an individual to understand the words spoken by another individual or those that appear on this page.

Together, Wernicke's and Broca's areas, along with other regions of the brain involved in aspects of language, have allowed humans to create the approximately 6,000 languages that are spoken today.

Although there is a general understanding of the brain regions involved in modern human language, what is less clear is the evolution of these areas. When one looks at the fossil record, it is evident that the knowledge contained within it is limited. In general, only the most durable parts of an organism fossilize. These include calcified materials such as bones and teeth. Only under rare circumstances will soft tissue be preserved, and so far no brain of any extinct species has ever been discovered. As such, the ability to interpret brain evolution is limited. Those that study brain evolution using the fossil record, paleoneurologists, use the various clues available on fossils. An important piece of evidence is the endocast.

An endocast is a cast derived from the endocranium or inside the skull where the brain resides. Although the external surface of the brain is distanced from the endocranial table of bone by cerebrospinal fluid, the endocranial surface does approximate the overall shape of the brain and in certain regions picks up the specific shape of a structure (for example, the course of a sulcus, the protrusion of a gyrus). Because of this intimate relationship, a cast of the endocranium may contain a large amount of information about the brain.

In some cases, sediment seeps into the skull during decomposition and hardens during fossilization to form a natural endocast. If the sediment seeps in before other forces act on the skull to possibly change its shape, the endocast preserves a reliable replica of the endocranial surface. Alternatively, a cast of the endocranium can be made after the fossil has been excavated. In both cases, the endocast can be used to determine overall brain size as well as general, and occasionally specific, features of the brain.

During human evolution, the brain has increased significantly in size from the 400-ml capacity of a chimpanzee brain to the 1400-ml capacity of the human brain. During the early part of the 20th century, it was assumed that increased brain size was the first adaptation to appear in human evolution. This would have indicated that early hominids would have been capable of some form of speech. However, after the discovery of *Australopithecus africanus* by Raymond Dart in 1924 and the subsequent exposure

of the Piltdown hoax, it was apparent that human brain evolution proceeded in a very different manner. Instead of the brain exploding in size early in hominid evolution, brain evolution proceeded in a much more gradual fashion, with brain size increasing only later.

Early hominids possessed brains that were little different in size from those of chimpanzees. Although this would indicate that early human brains functioned like those of their ape ancestors, this might not be the case. Endocasts from early hominids indicate that the brain underwent some form of reorganization once hominids were adapted to a bipedal posture. Although there is no indication that early reorganization included adaptations for language areas in the brain, it is possible that the changes that did occur laid the groundwork for later changes leading to the development of Broca's and Wernicke's areas.

Broca, and later the linguist Noam Chomsky, proposed that the human language areas represent an "organ" unique to humans. This philosophy of the uniqueness of human language and the structures responsible for it dominated much of linguistic and neurological study until the late 1980s, when it was discovered that there is no isolated language organ. Instead, it was found that there are language-related areas in many different parts of the brain that are connected to each other by vast neurological pathways. This alternate view of language and the brain meant that language might not have evolved *de novo* and at a single time in human evolution but that, instead, its history is much more complicated.

The German neurologist Korbinian Brodmann produced cytoarchitectural maps of the human brain during the early part of the 20th century. The area described as Broca's area was assigned to Brodmann's areas 44, 45, and 47. From his studies, it was possible to measure precisely the boundaries of this region and other regions for study in anthropology, medicine, and other fields. A few years later, Brodmann produced the same type of maps for the brains of great apes, identifying a region as area 44, implying that it possessed the same cytoarchitecture as that of modern humans. Brodmann did not think that chimpanzees having an area 44 in their brain meant that they possessed the same speech motor skills as did humans. Moreover, neither did his successors who found similar results. However, the presence of an area 44 in chimpanzees, an area clearly related to

Broca's area in humans, indicates that the precursors of brain language areas were present in the ape–human ancestor.

A second line of evidence indicates that some of the regions in the brain for language, and thus the rudiments of language, are ancient comes from a 1998 study by Patrick Gannon and colleagues that demonstrated the presence and asymmetry of a structure, the planum temporale, in the parieto–temporal region of the brain in chimpanzees. The planum temporale is within Wernicke's receptive language area in humans. Its presence in chimpanzees, as well as in gorillas and orangutans, indicates that some of the components for higher levels of communication are ancient. Moreover, the finding that the feature is asymmetric is also significant.

Because some features thought to be entirely unique to modern humans have been discovered in chimpanzees and other primates, it had been thought that one unassailable feature of the human brain is the asymmetry displayed between the left and right cerebral hemispheres. In general, chimpanzee brains, as well as those of other nonhuman primates, are symmetrical in appearance. In this case, the left and right sides of the cerebrum appear to be equal in size. In humans, however, the brain is asymmetrical, such that one portion of the brain is measurably larger than the other side of the brain. This asymmetry in humans is related to the division of cerebral functions between the left and right sides of the cerebrum. Thus, whereas speech production may occur in Broca's area on the left side of the brain, the right side may assume some other aspect of language. In this fashion, it is thought that the brain can process information efficiently by not first needing to integrate that information traveling to redundant areas. This is what makes speech fluid and abundant.

With the knowledge that chimpanzees possess brain areas resembling those found in humans for language and that these areas are often asymmetrical, it is possible to assume that language did not arise only within modern humans. Instead, as with other aspects of human evolution, language likely evolved over time, becoming more elaborate as structures in the brain and throat changed.

The first indication of modern-like human language areas in the fossil record may have been some 2.5 million years ago with *Homo habilis*. However, data from this time period are very incomplete, making any judgment of the neurological state of early

Homo all but impossible. It appears likely, however, that there were few changes in the brain of *H. habilis*, indicating that the development of language areas did not appear until *H. erectus*. This is due in part to the relatively small increase in hominid brain size from 6.0 to 2.0 million years ago. In addition, the features that are discernible on endocasts for language lack the asymmetry seen in modern humans. For example, according to research performed by Ralph Holloway, Broca's cap, an endocast feature that corresponds to a portion of Broca's area in the brain, is symmetrical in chimpanzees and early hominids, whereas it is asymmetrical in modern humans. This does not appear to be a consistent asymmetrical feature in the fossil record until *H. erectus*.

The appearance of Broca's cap in the fossil record suggests that the neurological components necessary for modern human speech are very old, dating to some 500,000 years ago or possibly earlier. At this point, the brain is approximately 1,000 ml on average, indicating that an increase in brain size may also have been related to the advent of language. Later reorganization of the brain, along with further increases in the size of the brain, likely led to changes important to fully modern human language.

The early development of modern-like language areas, such as the planum temporale in the brain and Broca's cap in endocasts, indicates that the neurological aspect of language is ancient in origin. However, as stated earlier, modern human language is a product of neurological and anatomical components. For example, although some researchers support the view that *H. erectus* and Neandertals were capable of language, others argue that the speech capabilities of premodern hominids were severely limited even though the neurological components for language may have been present early on. Thus, although species such as *H. erectus* likely had language, they were incapable of producing the range of sounds found in modern human speech. This limitation may have hindered the development of complex speech and further adaptation of brain structures for speech until the larynx evolved into the form seen today.

By the close of the 20th century, anthropologists had made significant advances in understanding the origin of language not known of during the first 100 years of human evolutionary study. Some of these advances were due to the discovery of new fossils. Many, however, were made through improved

techniques of observation such as computed tomography (CT) and magnetic resonance imaging (MRI).

Today, much of the focus on the origin of language is in the study of great apes. Studies of chimpanzee communication skills by researchers such as Savage-Rumbaugh continue to provide important data on the mental abilities of the closest living relative of humans. Moreover, understanding the full capabilities of the chimpanzee mind provides the most important line of evidence as to the abilities of the ancestors of modern humans.

Additional lines of study include elucidation of the ape brain. As continuing research has shown, the brains of chimpanzees appear to share more with humans than they do with other primates. This indicates that much of what is thought to be unique about the human brain has instead been exapted from the ape brain. Much research is still needed in this area, however, before there is a full understanding of what any possible similarities might mean.

ORIGIN OF LANGUAGE

Most scientists agree that one of the main characteristics that separates humans from other species is humans' ability to use language, both spoken and written. Many theories have been advanced as to the origin of language. There is still no one theory to which all anthropologists subscribe.

Some believe that humans began talking early in the scheme of things. Creationists think that God created humans with a full-blown language ability. This would fit with the biblical accounts of Adam and Eve conversing in the Garden of Eden.

Many other scientists, however, subscribe to a theory that language was a later development in the evolution of humans. But they cannot agree on the way in which language originated. There are many theories that are divided into imitation hypotheses and necessity hypotheses. Imitation hypotheses state that language was acquired by humans imitating naturally occurring sounds. Necessity hypotheses hold that language originated as a response to an acute necessity in the community.

Some believe that language developed as humans named objects, actions, and phenomena after sounds they heard in real life. This would include words such as *crash* and *boom*. There are two problems with this hypothesis. First, words that imitate sounds (onomatopoeia) make up a very small part of the vocabulary of a language. Second, the words for these sounds differ in different languages.

Some think that the first words were involuntary exclamations of pain, hunger, pleasure, and dislike. This theory is subject to the same limitations as the first theory given that exclamations make up only a small part of any language and that the exclamations for the same things tend to vary from one culture to another.

According to a third theory, which was never widely accepted, vocabulary developed by humans imitating animal sounds. This theory has the same inherent problems as the first two theories. The last imitation hypothesis, put forth by Charles Darwin, states that speech may have developed when

humans tried to imitate with their organs of speech the gestures that they made. Darwin himself was skeptical about this theory. Also, human gestures differ greatly from culture to culture.

One of the necessity hypotheses states that language developed out of a need for warning signals. Words such as *help*, *look out*, and *run* might have developed early. Some scientists think that language was based on human cooperative efforts. Perhaps the earliest language was a chorus of chanting to stimulate collective efforts such as moving big stones and repeating war chants to bolster courage.

Another interesting hypothesis takes into account the fact that emotions can be communicated by gestures and facial expressions. When humans wanted to contradict this body language, they came up with language to deceive other humans.

None of these hypotheses explains how grammar developed in a specific pattern. This does not seem like a random development given that all languages have complex grammatical structures.

None of these theories can be either proved or disproved, so no definitive conclusion has been reached as to the origin of language.

LANGUAGE, TYPES OF

Language types and language typology refer to characterizing languages of the world by similarities and differences in their structural forms and in their functional uses. They also refer to characterizing them according to language families where there is evidence that the languages have common structural relationships that are consistent with some “parent” language (i.e., genetic classification). These two kinds of language typologies do not usually involve, to any great extent, focusing on social context or cultural variations of language use and language change that are typically studied by sociolinguists and anthropological linguists. Yet having knowledge of the characteristics and varieties of language (or languages) used in a society helps to inform the work of both groups

of researchers as well as others that fall under the umbrella of applied linguistics.

Most of the work on language typology involves differentiating spoken languages, but there is a considerable focus on characterizing writing and signed languages as well. With William Stokoe’s efforts during the mid-20th century to secure recognition for American Sign Language (ASL) as a true language, typology of sign languages around the world has been a particularly vigorous pursuit.

Types of written language are a special case because, unlike spoken language and signed language that are directly interactive, much writing is generated without actual “in time” interactions and is, as David Crystal pointed out, space-bound and static. Societies that speak different languages may use the same writing system. For example, Cyrillic script is used by several Slavic languages and some non-Slavic languages.

Identifying Types of Language

Although human languages are grouped as spoken or signed, there is a wide range of characteristics in the world’s languages that make the task of subclassifying them into types within these categories quite difficult. Given that there are estimates of between 3,000 and 10,000 spoken languages, the development of language varieties and the change that can occur in languages over time add to the dilemma of approximating typologies. The same is true for signed languages in the world. Among the many systems that linguists have used to try to manage complex combinations of linguistic variables, there is a basic focus on how languages differ in their structures and in their formal use.

Crystal provided a detailed explanation regarding spoken language typology and distinguished between two major approaches to the task: differentiation and the search for language universals. The latter construct is especially associated with Noam Chomsky, who has explored language characteristics that could generate a set of rules universal to all languages. Rather than looking at the ways in which languages are different, Chomsky has been more concerned about those things that are in common in a generative grammar that helps to understand the human mind.

The second approach to language typology is differentiation, and it is this approach that is applied not only to characterize language structures but also to

indicate how languages are the expressions of societies and cultures. In other words, by differentiating languages, we can locate patterns of linguistic and societal development and we can formulate theories about societies living in specific geographical areas. Language and culture may be artificially separated for study, but they are actually inseparable for understanding the ways in which people create communities and live in them. Crystal cautioned, however, that there is no evidence that “languages of a particular type are inevitably associated with particular geographic areas or with people of a particular ethnic or cultural group.”

Structures for Typology of Language

One way of designating language structures for differentiating languages consists of three divisions: grammar, semantics, and phonology. The category of grammar includes words (morphology and word classes), phrases, and sentences. Anatole Lyovin described another set of possible options in six categories of typology: phonological, morphological, syntactic, lexico-semantic, holistic, and sociolinguistic. These categories are derived from theories proposed to provide an adequate classification of the world's languages. All categories but the sociolinguistic category deal primarily with the implications of language universals. In the case of sociolinguistics, several frameworks have been proposed that really strive to differentiate languages where there is considerable variability in language use rather than looking at universals.

Kinds of Grammar Typology

A grammar can be viewed, in a very basic sense, as a framework for describing the ways in which the components of a language (words, phrases, sentences) are positioned and operate so as to achieve meaning. Crystal distinguished among six different types of grammar that address distinct purposes: descriptive, pedagogical, prescriptive, reference, theoretical, and traditional. For example, he described a prescriptive grammar as one that focuses on socially correct uses of language such as that of Henry Fowler's *A Dictionary of Modern English Usage*.

Noam Chomsky drew attention to issues of grammatical complexity that are not understood merely by thinking of grammatical representations as maps or guides to identify the appropriate forms of a language.

He distinguished between the surface structure of a sentence and its deep structure. One classic English sentence pair that he used in a demonstration of these two structures is *I* “I persuaded John to leave” in contrast to “I expected John to leave.” In this case, both sentences have the same surface structure but different deep structures. Noting distinctions such as this informs linguists in the discovery of rules to designate a set of language universals across languages.

Syntactic Typology and Grammar

Grammatical frameworks characterize the forms and kinds of words that exist in a language and the ways in which they are used and ordered in other structures of language, particularly in the sentence, which is a main form that dominates language typology. For example, languages such as English have a common pattern of subject-verb-object (SVO) in the ordering of words in sentences, although there are other ways permitted for ordering words into sentences, and English has particular word orders for phrases, as in positioning color words, (for example, *big yellow ball*). Other languages in the world follow one of five other identified word patterns, and sometimes they permit more than one pattern as part of common language ordering. It is estimated that more than 75% of the world's languages follow the SVO pattern.

Some languages are typified as agglutinating, whereas others are typified as inflecting, synthetic, or fusional. The grammars of these kinds of languages are characterized by the ways in which sentences and words occur as strings in which there might be markers for tense, gender, person, number, voice, and/or mood. For example, *amant* in Latin is translated as the third-person plural present tense for the word *amo*, meaning “to love” (i.e., “they love”). Words in Turkish, an agglutinating language, contain a root or stem and markers that account for characteristics such as plurals and possessive pronouns. The words also follow vowel harmony rules so that certain forms of pronouns, for example, may be spelled differently to be attached to the stem word and plural marker as in the following: my banana = *muzum* (muz + um), but my bananas = *muzlarim* (muz + ar + im).

Lexicosemantics and Semantics

A second characteristic that is applied to differentiate languages is semantics or the meaning of utterances

in languages. How words are used to specify particular meanings, and the availability or lack of availability of words in various languages, is part of the study of lexicosemantics. For example, studies regarding color words in languages where societies live in distinctively different geographic areas (for example, island societies and the color *blue*, Arabic nations and words for *camel*) might have consequences for the linguists to create accurate schemata to classify language types by understanding word use, semantic interpretation, and the availability of words.

Characterizing languages by their semantics has to do with the manner in which meaning is expressed. There are considerable data involving the study of words and their interpretations within grammars, even though a preferred approach for typology is to work on syntax. Languages can be differentiated semantically according to the ways in which words are used, the prosody that is used, and how the grammar is constructed as well as pragmatically. A statement in English such as “Let him have it” can be interpreted differently depending on the emphasis or the lack of emphasis (i.e., prosody) on the word *him*. An ambiguous sentence such as “Bill told John that he loved Mary” will be interpreted according to a grammatical principle in English that designates the function of the subject noun in each clause to be approached as an equivalent (i.e., parallel function). Sentences such as “Mary put the rug next to the chair and sat on it” will take on a preferred interpretation according to the “usual” way in which things work in the world (i.e., pragmatics).

Crystal pointed out that there is an uncertain boundary between syntax and semantics that poses a special problem in linguistics; thus, differentiating among language types more accurately can often be enhanced by studying the sociolinguistic or ethnographic dimensions of language use in particular contexts. This is something that was recognized by the anthropologist Dell Hymes, who proposed an ethnography of speaking as a construct for understanding societies and communities of speakers. Two types of language that would necessitate study in this way are pidgins and Creoles. These languages were formed through conditions requiring communication between groups of people who had very different languages, mostly for trade purposes (for example, French traders and the natives of New Caledonia in the Southwest Pacific).

Phonological Typology

An interesting category for language typology is that of phonological classification. Applying rules for speech sounds that can occur in human languages provides a special perspective on the differentiation among spoken languages. Chinese, for example, is a set of languages that are described as tonal. In Mainland China, there are hundreds of languages and dialects that are classified as “Chinese,” and all of these share tonal characteristics. Some of the languages in Chinese have simple tonal patterns, and others are more complex. Every syllable has a tone that distinguishes the meanings of words, and these tones are affected by the chains of syllables in speech. Tonal variation is the main characteristic that differentiates among the dialects (languages) in spoken Chinese. It is a common writing system that helps the members of a great number of Chinese-language communities to understand one another.

Typology of Sign Languages

Much of the typology of sign languages has been derived from the structural characterization of ASL. Designations of grammar, semantics, and phonology have been applied and interpreted through formal linguistic analysis, and subsequently the classifications in ASL have been used to compare and type other sign languages in the world. This study has been a relatively new endeavor, beginning for the most part during the latter half of the 20th century.

Researchers approached the field through processes of differentiation as well as by looking for language universals. Because sign languages were not given equal status with spoken languages for a considerable part of history, it was important that the characterization of ASL account not only for the formal structures but also for language use and sociolinguistics. Anthropological linguists, such as James Woodward and William Washabaugh, explored relationships between ASL and other sign languages used by deaf persons in countries besides the United States. Their work, along with that of ethnographers such as Gerner di Garcia, has drawn attention to the sociolinguistic dimensions of language typology as seen through communities whose members use sign language.

The Lapps, or Sámi as they prefer to be called, reside in a vast area of land that is nearly 400,000 square kilometers and crosses the boundaries of four countries: Sweden, Norway, Finland, and Russia. They are the oldest known inhabitants of Finland. The Sámi are in the minority in each of these countries and are often faced with discrimination. Their territory once extended even farther to the south, but as the rest of the world's population grew and moved closer to the Sámi, they retreated farther north. To the Sámi, the name "Lapp" is derogatory.

It is difficult to determine the exact population size of the Sámi due to the differing methods of determining Sámi ethnicity. For instance, in Finland, language is the primary method used. Anyone who speaks Sámi, or whose parents or grandparents speak Sámi, is considered to be Sámi. However, in Norway and Sweden, reindeer herding is used to determine nationality because the Sámi are known for this mode of production.

Although the Sámi are generally known as reindeer herders, there is actually a great deal of variation within the Sámi population regarding their primary mode of production. The Sámi can be divided into five different groups based on their geographic locations as well as on their primary modes of subsistence. One group is the Coast Sámi, whose economy is based primarily on fishing and who reside in Norway. Another group is the Forest Sámi, whose economy is based on hunting and trapping, supplemented by fishing, and who live primarily in Sweden and Finland. Another group is the Mountain Sámi, whose economy is based on reindeer herding and who live in the central and northern areas of Norway and Sweden. Another group, the River or Fisher Sámi, are known for farming and cattle raising. They also fish and herd reindeer to supplement their incomes, and they live in Norway and northern Finland. The final group, the Skolt and Kola Sámi, live in the most eastern areas of Norway, Finland, and Russia that are inhabited by Sámi. Their economy is based on both forest and sea products. They have been the most influenced by missionaries, especially the Russian Orthodox Church.

The Sámi culture is believed by many to be in danger. The primary obstacle facing the Sámi with respect to maintaining their cultural identity is the fact that they live in four different countries, making it difficult for them to develop their own separate form of organization. Furthermore, they speak at least six different languages that are closely related to Finnish. In the past, the Sámi have had difficulty in maintaining their languages because they were not allowed to use their languages in formal schooling of their children or in official governing processes and procedures. Moreover, in some areas, the Sámi have been experiencing population decline.

However, as a result of organization by the Sámi, they are now able to use their languages in schooling under the Finnish Schools Act of 1985. Norway and Sweden also have laws to support the use of Sámi for education as well as for governance. Linguists have also been studying the languages of the Sámi, and books and movies have been produced in Sámi. This will likely help to preserve their culture. The Sámi Council now represents all Sámi and participates in the World Council of Indigenous Peoples.

LASCAUX CAVE

On September 12, 1940, in an oak forest just outside the small town of Montignac in southwestern France, four schoolboys crawled into a hole in the ground that had been exposed by the roots of a

falling tree. Once inside, they crawled several dozen yards along a dark passage before finding themselves in a cavity across whose walls cascaded large and vibrant polychrome images of a variety of mammals, notably aurochs, the extinct ancestor of today's cattle. The boys had discovered the cave of Lascaux, now generally acknowledged to be the finest among several hundred decorated caves known from the last Ice Age of southern France and northern Spain.

Lascaux, a solution cavity in Cretaceous limestones, is decorated principally in three areas: the Hall of Bulls, into which the schoolboys stumbled; the narrow Axial Gallery beyond it; and the Lateral Gallery, which opens to its side. Paintings have been preserved mainly in parts of the cave where the walls are coated with a layer of "cauliflower calcite" that trapped the particles of mixed pigment daubed or blown onto them. In other areas, notably the Lateral Gallery, thousands of finely incised animal engravings are preserved, but only tiny traces of paint remain.

Source: © Kathleen Cohen.

The painted animal images are beautifully observed but are also rendered using a variety of sophisticated conventions found elsewhere, for example, leaving an unpainted space between the far-side legs and the body of an animal seen from the side to produce the effect of perspective. Also as elsewhere, the animal images are accompanied by a host of abstract signs whose significance has been variously interpreted. Most likely, they formed part of a larger symbolic system that equally embraced the animal images, which in this cave are predominantly of horses, although the total fauna represented is quite diverse.

Painting and engraving of animal and abstract images in caves (and the decoration of “portable” objects) started in the Franco–Cantabrian area at some time before 32,000 years ago and continued at least intermittently until the end of the last Ice Age (which witnessed a radical climate-mediated erosion of the artists’ economic base) some 11,000 years ago. The artists themselves were Cro-Magnons, early European *Homo sapiens* who led a hunting-and-gathering lifestyle of remarkable technological and probably social sophistication and who left evidence of symbolic activities of many kinds, including notation and music as well as graphic art. Lascaux itself was evidently decorated by a team of specialists who rigged up scaffolding to undertake their work and who worked by the light of dozens

of rudimentary fat-burning lamps that they left behind. Exactly what the art was created *for* is unknown.

Stylistic, technological, and pollen evidence, as well as some radiocarbon dates, suggests that Lascaux was decorated some 17,000 years ago, just after the peak of the last Ice Age but during a brief respite from the most severe climates of that period. Excessive visitation following its discovery led to deterioration of the cave’s condition, and in 1963 it was closed to

the general public. It is currently totally closed due to continuing conservation concerns.

LAW AND ANTHROPOLOGY

Law and anthropology (or legal anthropology) examines the relationship among society, culture, and law in societies at various levels of political, economic, and social complexity. Legal anthropology is a sub-field of the discipline of anthropology; however, its subject matter is also a focus of interdisciplinary analysis in fields such as criminal justice, law, philosophy, and sociology. These academic disciplines analyze the cultural context of laws and rules, the processes of their development, how different

societies structure competition and conflict, the manner in which legal institutions function to maintain social control, and the range of mechanisms used for settling disputes and maintaining social cohesion. In addition, applied legal anthropologists, such as forensic anthropologists, use anthropological information to provide direct assistance regarding legal issues.

Scholars credit Sir Henry Maine (1822–1888), an English comparative jurist and historian, as the founder of legal anthropology. In *Ancient Law*, Maine developed a theory positing that the development of legal systems was the key to social evolution. Maine argued that as society progressed from custom to law, political organization evolved from one based on kinship to one based on territory. Accompanying such movement was the emergence of the “individual” as separate from the group and the replacement of “status” (family) with “contract” in the modern nation-state. Scholars criticized the evolutionary bias in Maine’s model of law, challenging Maine’s view that the modern nation-state is necessarily the most civilized stage of development. However, for decades *Ancient Law* remained the preeminent work on the nature of “primitive” legal institutions.

The Emergence of Modern Law and Anthropology

Modern legal anthropology developed during the 20th century with the publication of several significant anthropology books and monographs devoted to law. These studies examined the legal ideas and practices of non-Western peoples, especially their approach to the management of disputes in their societies. Research conducted by the anthropologists Bronislaw Malinowski (1884–1942), E. Adamson Hoebel (1906–1993), and Max Gluckman (1911–1975) were key to the development of legal anthropology.

Bronislaw Malinowski and Norms of Reciprocity

Malinowski was the founder of a theoretical perspective known as structural functionalism. The premise of structural functionalism, as articulated by Malinowski, is that every component of social structure, including law, functions for the good of the whole society and every component of social structure interconnects to form a well-balanced system. In *Crime and Custom in Savage Society*, one of several monographs written by Malinowski on the Trobriand Islands of Melanesia, Malinowski conducted systematic research

on tribal law and applied a structural–functional analysis to the study of the various forces that make for order, uniformity, and cohesion in a “primitive society.” He criticized earlier anthropological perspectives that assumed that the community completely dominates the individual in primitive societies, that is, that the individual is simply a passive obedient responder to the customs and commands of the community. Malinowski argued that a lack of fieldwork led anthropologists to these erroneous conclusions about law in these societies.

Using an ethnographic approach, Malinowski sought to understand what kind of law exists in Trobriand society and why members of the society follow that law. His observations led him to criticize the assumption made by many scholars that law in such societies consists primarily of strict prohibitions and harsh punishments resembling criminal law. Instead, Malinowski’s research led him to recognize the importance of reciprocity, an exchange system based on mutual services between individuals and groups, as the basis for law and, consequently, social order. Malinowski posited that the obligations associated with reciprocity have the social function of safeguarding the continuity and adequacy of mutual services. He found that obligations associated with reciprocity are the primary social bonds in Trobriand society. Furthermore, the public and ceremonial nature of exchange, as well as the desire for individuals to achieve prestige, reinforces these bonds. Based on his observations, Malinowski called for a broader definition of law, one that recognized law as a body of binding obligations kept in force by the specific mechanism of reciprocity and publicity inherent in the structure of society. Given this broad conceptualization of law, Malinowski asserted that specific, formal legal institutions are not necessary in every society.

E. Adamson Hoebel and the Case Study Method

Hoebel was an ardent proponent of the collaboration between the two disciplines of anthropology and law. In *The Cheyenne Way*, Hoebel collaborated with a law professor, Karl Llewellyn (1893–1962), to examine the methods used by the Cheyenne for the legal resolution of intratribal conflicts. In studying the Cheyenne, Hoebel and Llewellyn developed a social science instrument for the recording and interpretation of dispute resolution among “primitive peoples” known as the case study method. This case study method consisted of examining in detail the

processes involved in settling “trouble cases.” In a typical trouble case, this included investigating what happened, what each participant did in relation to the dispute, what steps were taken by other persons, the final outcome, the reasoning of the deciders, and the effects of the decision on the parties themselves, on future trouble cases, and on the general life of the group as a whole.

Hoebel and Llewellyn advocated for the case study method of investigation because they believed that the two other methods of investigation that were available to researchers had serious methodological weaknesses. The first, the ideological approach, emphasized concentration on norms or rules that express ideal patterns against which researchers can measure actual behavior. The emphasis of this approach is to investigate what people think are the rules of their society. Hoebel and Llewellyn pointed out that in some societies people do not think in terms of rules and, therefore, are unable to identify the rules of their society. Moreover, in societies that do think in terms of rules, a statement of the rules might not explain decision making adequately; that is, precise conformity to the norms is the exception rather than the rule. This divergence between norms and outcomes could result from normative ambiguity or normative conflict. Hoebel and Llewellyn also found the second approach, firsthand observations of actual behavior, to be seriously deficient in two respects. First, they believed that studies using this method contained descriptions of behavior that were overgeneralized and did not give a complete picture of how disputes were resolved. Second, these studies tended to concentrate on substantive law, or what the rules of the society are, instead of procedural law that examines the process for settling trouble cases. Hoebel and Llewellyn believed that the case study method overcame the limitations of these two approaches. They argued that by using the case method, researchers are able to identify the phenomenon of competing norms, overcome the inability of individuals to articulate norms, observe the divergence between stated norms and actual outcomes, and examine the actual process used in trouble cases. The study of actual legal cases as the unit of analysis for investigation also enables researchers to generalize from particular cases and, therefore, to understand the legal system of a society. It also enables researchers to understand legal change through studying comparative legal dynamics.

Max Gluckman and Legal Reasoning

Gluckman conducted extensive research among the tribes of Central and South Africa. In *The Judicial Process Among the Barotse*, Gluckman focused on the dispute settlement process of the Lozi, a society consisting of a number of interrelated ethnic groups located along the Zambeze River in Barotse Province in western Zambia. He systematically studied the Lozi court in action, listening to cases and the legal arguments presented as they unfolded. From an analysis of the cases and legal arguments, he sought to extract the way in which Lozi judges approached their task, how they assessed evidence, what sources they drew on in making their decisions, the logic of their arguments, and how they applied legal rules to social life. To achieve these objectives, Gluckman distinguished Lozi norms that were special to their society from the logical principles that judges used to decide what norms to apply in court and how and when to apply these norms. Gluckman believed that the results of his research demonstrated that the judicial process used in Lozi courts represented logical principles or modes of reasoning found wherever individuals apply norms to settle disputes, that is, that indigenous African legal systems and practices were as rational as those found in Western societies. Therefore, Gluckman argued that although the premises of the Lozi court were different from those of Western courts because the social context of the society was different, the logical principles used and the reasoning process were the same as in Western courts.

Critics challenged Gluckman’s universalistic notions about logical principles and modes of legal reasoning. In particular, the anthropologist Paul Bohannan asserted the importance of cultural difference and uniqueness, even in the legal principles and process of legal reasoning used to settle disputes. Bohannan argued that law is an expression of unique cultural premises. He believed that anthropologists should not apply Anglo-American categories to the study of non-Western societies because using such categories prevents understanding another culture. Instead, he advocated the use of native legal terms that perhaps are not translatable into English but provide a nondistorted understanding of the judicial process of non-Western societies, including the legal reasoning used to arrive at decisions. The task for the anthropologist is to explain the meanings of native legal terms as part of the reported research. For critics such as Bohannan, comparative law was an opportunity to

examine cultural difference, and the analysis of cultural difference is a central purpose of anthropological research.

The Broadening of Law and Anthropology

Studies in non-Western societies continued during the 1960s and 1970s, with an increasing number of anthropologists advocating for studying the processes by which disputes are resolved. This approach often emphasized a choice-making (or rational) model of behavior in which people could use law in a variety of ways to represent their own interests. This approach also examined the process of dispute resolution within its sociocultural context, with anthropologists observing that people often managed their legal disputes through a system of informal negotiated settlements among parties rather than through court-centered approaches. The law as process model challenged the long-standing emphasis in legal anthropology on rules of adjudication as the primary focus of research. In response, some scholars attempted to synthesize the rule-centered approach with the law as process approach. An additional outcome of the process model of law was an emphasis on legal pluralism, that is, the recognition that many types of dispute processing could exist in the same society. Anthropologists began to understand that societies contained other sites where norms were generated and social control was exercised besides the state. In such a system, the social reality may consist of behaviors that are congruent with rules and other behaviors in other sites where people exercise choice to benefit their own self-interests.

The subfield of legal anthropology, however, has broadened its domain in several other, more fundamental and significant ways than simply an emphasis on legal process and pluralism. Most notably, legal anthropology now studies industrial countries and has expanded its scope of inquiry from local legal analysis to national and transnational legal matters. Legal anthropologists study areas such as the field of human rights, international treaties, and other issues that anthropologists did not address in earlier works grounded in a community-based conception of anthropology. Such research entails a greater concern with issues of stratification and power. It also means that anthropologists may openly question the legal rules set by the state when they view these rules as detrimental to the poor and the oppressed.

These anthropologists report persecutions and other atrocities of peoples, and they take positions on the issues they address. Law as ideology becomes a way of contributing to the social construction of a just world. An example of such an approach is anthropologist Laura Nader's criticism of the addition of the informal alternative dispute resolution (ADR) in American courts as a response to the perceived needs of the poor and of those who had minor legal claims. Nader referred to ADR as a kind of coercive "harmony ideology" and argued that the poor should have access to the courts rather than being forced into a mediation setting because the legitimacy of a legal system depends on providing access to the courts for all. Furthermore, she asked what coercive harmony ideology signified about the inequalities of American society. Nader also applied the idea of harmony ideology to interpret her work on dispute resolution in a Mexican Zapotec mountain village and argued that the reason why people presented themselves as resolving all disputes harmoniously was part of a political strategy to keep colonial authorities from meddling in village affairs. Thus, Nader was able to draw parallels between the power and stratification situation of colonial peoples and the poor in industrial countries.

As legal anthropologists began to study industrialized nations such as the United States, the theoretical orientations of other social sciences and law contributed to their perspective and understanding. Legal anthropologists saw the limitations of the structural-functional paradigm in a world where transnational processes exercise enormous power over people and nations. They also recognized the limitations of a dispute processing approach that does not take into account its wider social context. By collaborating with other disciplines, such as law and sociology, other paradigms provided alternative explanations of the role of law in culture and society. For example, in legal scholarship, critical legal studies examines the way in which law maintains power relationships by creating images of social relationships that appear to be fair due to the authority and legitimacy that the law gives them.

Finally, globalization has become an important theme within legal anthropology scholarship. Anthropologists consider the impact of globalization on social relations in several different kinds of context. For example, one context for examining globalization is that it is a form of postmodern colonialism, that is, a form of domination in which the worldwide production and consumption of cultural products is removed

from the contexts of their production. Another context is to examine justice issues within the context of globalization. This includes analyzing the tension between local formulation of human rights and its global counterpart, that is, the ideology of international human rights. It often also includes taking a position on the definition of human rights and what kinds of political system can provide these rights.

Law and anthropology examines the complex processes through which laws shape human life. Early studies by legal anthropologists reflected a community-based conception of anthropology. Today, law and anthropology has expanded its scope of inquiry to include national and transnational legal matters. The role of the anthropologist has also changed from one of simply being an observer and reporter of social relations to one of, at times, taking a position on justice issues.

RIGHTS OF INDIGENOUS PEOPLES TODAY

Securing rights for indigenous peoples around the world is an important issue today. Great strides have been made in this direction, but much work remains to be done.

According to the United Nations, human rights are those rights that are inherent to the human being. Every human should have these rights, without being discriminated against because of color, race, religions, gender, language, political opinions, national or social origin, property, birth, or other states. These rights are founded on respect for each person's worth and dignity. They should be applied to all people without discrimination. No one's rights should be taken away unless he or she is convicted of a crime by a court of law. The International Human Rights Law has been adopted by the United Nations. Many nations have also adopted laws that formally protect the basic rights of individuals.

Indigenous peoples still have concerns about their rights. Representatives from around the world voiced many of these concerns at the Permanent Forum on Indigenous Issues in May 2002. Representatives came from areas as diverse as Alaska, Columbia, Scandinavia, Siberia, Africa, Australia, and Indonesia. Reported abuses of the human rights of indigenous peoples included usurpation of land, genocide, and proscription of traditional languages. Groups of hunters, gatherers, and traditional farmers from Africa and the Amazon Basin charged that their lifestyles are being wiped out as the land is taken over for extraction of resources, grazing, and hydroelectric projects.

Several news releases in early 2005 addressed human rights for indigenous peoples in different areas. In *Nigeria World*, Samuel Bayo Arowolaju claimed that indigenous peoples are being denied political rights in Nigeria. He called for a national conference to discuss the problems. Irene Kahn's article in the *Toronto Star* addresses "Canada's shameful failure." She reported that indigenous women in Canada face a much higher rate of violence and discrimination than other women in the country.

The same week in March 2005, the European Parliament voiced concerns over persecution of the Mari people in Russia. Most of the indigenous Maris were opposed to the reelection of President Leonid Markelov in 2004. Since the election, Maris who spoke out against Markelov claim to have suffered illegal dismissals and violent beatings, some resulting in death.

Although many people in many places are working toward securing human rights for all indigenous people throughout the world, there is still much work to be done.

LAW AND SOCIETY

Law and society designates a three-way concern with the nature of law, society, and the relation between them. Two main approaches have been important: one ultimately rooted in the law and legal theory of the Roman Republic and the other ultimately rooted in the law and legal theory of the Roman Empire. This entry describes the bases of the tradition, its transformation into the 19th-century debates that framed the emergence of sociocultural anthropology, and its main representatives in anthropological theory.

Roman Law and Legal Theory

Roman law is a complex body of substantive laws, legal doctrine, and theory about law and society that began in the Roman Republic and has evolved continuously since. The general view of law in the ancient Mediterranean world was that it was the “will of the gods.” It was, therefore, not something that mortals could create. It had to be something they found. Different societies used different theories of how this was to be done.

Rome was always a class-based society with two main classes. Patricians were a military aristocracy whose members held large estates that they farmed with unfree labor, slaves, and plebes. Plebes were not uniform, but their main interests were those of small-scale peasant farmers.

Republican legal theory was social constructionist with a presumption of individual freedom and rationality. A “republic” is *Res Publica* (a public thing). There were several key ideas. Officers were elected for fixed 1-year terms. At first, the chief officer was the praetor, who was chief magistrate and general of the army. His power to command was his *imperium*. Candidates for magisterial office described the laws they would enforce, so the vote was for both. The principle that connected the idea of law as the will of the gods to this system of election was *vox Populi vox Dei* (the voice of the people is the voice of the gods).

The popular voice was safeguarded by checks and balances. Soon after the republic was initiated, the office of consul was added above the praetor. The consul was always a divided office, that is, one office occupied by two people. To do anything, the two had to agree. Still later, the office of tribune was added in response to the demand of the plebes. The tribune was elected solely by the plebes and could block any action of a praetor or consul that was adverse to plebian interests.

Magistrates were balanced by the senate, consisting of men who had been through the elected offices and had not done anything to merit censure. Although the magistrates could initiate wars, only the senate could receive ambassadors and make peace.

Finally, the law authorities were separated from the law enforcers. The key text and symbol of the process was the XII Tables, attributed to a committee of 10 men representing patricians and plebes on display in the Forum Romanum. It was not a code but rather a set of key legal problems and solutions that implied what the basic legal principles were without stating them. For the rest of the law, a legal archive was maintained in the college of the Pontiffs, headed by the pontifex maximus.

The Roman Empire was constructed out of the offices of the republic by Augustus. Having been elected consul repeatedly, Augustus gave up that office to be appointed proconsul for life with an extended *imperium*. Proconsuls were appointed by the senate and did not have fixed terms. He then was elected tribune and finally also was appointed pontifex maximus. This obliterated the checks and balances and established the system known as the principate, which very quickly became the hereditary single office of imperator (emperor).

With elections ended, the constitutional principle could no longer be that the voice of the people was

the voice of the gods. It became instead “The emperor is the voice of the law.”

Imperial legal theory developed around the idea of a conflict between state interests and individual interests. This was embodied in the sequence of efforts to establish uniform imperial codes, beginning mainly with Theodosius and culminating in the *Corpus Juris Civilis* ordered by Justinian. The organizing principle was hierarchy, that is, a hierarchy of civil laws that followed by logic from first principles in a state that was a hierarchy of obedience to the emperor. The compilers did not write new law but rather rearranged the law that already existed according to what they argued were universal logical principles. When the *Corpus* was completed in 529 CE, Justinian ordered all other law books destroyed.

Although the *Corpus* disappeared from European administrative life soon after it was promulgated, republican law lived on. It had always been fundamentally the law for a *civitas*, and it persisted in both the original Roman cities and the *colonias* that had been sent out to conquered areas. These were usually located in previous large settlements where the Roman colonists lived side by side with the original inhabitants and brought them under Roman protection. When the empire collapsed and the power relations reversed, the Romans were protected in turn. Eventually, the populations and legal systems merged to form the European nations that are recognized today.

Rebirth

The conflict between empire and *civitas* redeveloped in Europe in three main contexts. First, in the 11th century, universities began to be established and offered law as a subject of study based on textual analysis of *Corpus Juris Civilis*, which was copied, extensively annotated, and widely circulated as a general legal standard. The second context was the development of canon law by the Catholic Church on the same model. The third was the “reception” of the 15th century, a widespread movement in Germanic areas to introduce substantive codes along the same lines. Because the principles of imperial law could not be extracted from their texts without also exposing the underlying principles of republican law, by the Renaissance both theories were once again in full flower and known to all educated people.

Enlightenment

Political, social, and legal philosophy as now recognized crystallized in debates over the epistemological basis of law governmental legitimacy between the reception and the 19th century. In this, arguments on the republican side were closely aligned with arguments for experimental science and philosophical skepticism. Those on the imperial side were aligned with the idea of deductive systems based on a priori or self-evident knowledge. On the republican side, these culminated in the Enlightenment arguments of Montaigne, Montesquieu, Smith, Hume, Kant, and the authors of the American Revolution. On the imperial side, comparable figures included Hobbes, Locke, the Scottish Common Sense philosophers, and Hegel. Of these two traditions, the former was clearly ascendant by 1800.

The 19th-Century Republican Tradition

The most direct path to the 19th-century anthropological conceptions of law and society begins with the historical jurisprudence of Carl Friedrich von Savigny (1779–1861). His subject matter was Roman law between the collapse of the empire and the reception, and his focus was not on texts but rather on courts and legal ceremonies as represented by court documents.

It was Savigny who traced the continued development of Roman republican law in Europe after the empire collapsed. He saw this as demonstrating that “law grows out of the life of the people,” at once an echo of Kant’s conception of law embodying the progressive growth of freedom of a community and a reaffirmation of *vox Populi vox Dei*. His philosophical and political manifesto was titled *Of the Vocation of Our Age for Legislation and Jurisprudence* (1814) and opposed a project to write a legal code for Germany on the Napoleonic model. He contended that laws constructed in such a way could never have the subtlety, complexity, and efficacy of law that grew naturally, or “organically,” from the perceptions and values of those to whom it applied—the spirit of the people, their *Volksgeist*.

For anthropology, the most immediate impact of Savigny was through the Grimm brothers, Wilhelm and Jacob. Both were his students. Jacob, the elder, began his studies in 1802 and was a research assistant for Savigny beginning in 1805. Since Savigny had

deciphered the history of Roman law in the German context, one obvious unknown concerned the German side of the relationship. One possibility was to use folkloristic materials collected from the less educated and presumably more conservative “folk” so as to find relics of an ancient *mythos* not originating in the Latinized culture of the upper or educated classes. To date this material, the Grimms adapted Savigny’s comparative method to the language of the stories. This led to the discovery of the “sound law” in the sequence of languages that leads from ancient Greek, to Gothic, to the varieties of modern German. The general method is still the basis of historical linguistics. The Grimms’ main work on law proper was Jacob’s *Deutsche Rechtsaltertümer*, published in 1828.

Savigny’s recognized successors in law included Theodor Mommsen (1817–1903), Frederick William Maitland (1850–1906), and Rudolph von Jhering (1818–1882). The first two revolutionized the history of law. Jhering revolutionized the analysis of law as such. Building on Smith and Kant, Jhering grounded his analysis directly in cognitive and social processes at the individual level. Two mutually complementary theses run through his work. The first is that law is created and maintained through self-interest. The second is that law grows out of the self-regulation of power.

Jhering argued that self-interest bids us to enter exchanges. Even exchanges are self-enforcing by mutual interest. But exchanges can become uneven. For example, suppose that I offer to pay you if you fix my plumbing. You fix it. Now I have fixed plumbing and what I offered to pay you. In this case, law is needed to provide an artificial interest in paying you to replace the natural interest that has been removed. This is what law is: a support to maintain required relations in other institutions, especially commerce, in those cases where they do not maintain themselves.

Jhering had two major successors of direct importance to anthropology: Eugen Ehrlich (1862–1922) and Hermann Kantorowicz (1877–1940). Ehrlich originated the term “sociology of law.” His central concept was the notion of the “living law” as those rules we have that are so firmly enforced that we can hardly think of violating them and that rarely or never actually require judicial action, for example, the rules of most workplaces. Kantorowicz’s perspective was very similar.

The Lawyer-Ethnologists

The more the sophistication of Roman Republican law became clear, the more important it seemed to be to ask where it originated. This was the question of the lawyer-ethnologists such as Adolphe Bachofen (1815–1887), Henry Maine (1822–1888), Lewis Henry Morgan (1818–1881), and John F. McLennan (1827–1881).

Bachofen had studied under Savigny at Berlin from 1835 to 1837; was appointed professor of Roman law at Basel in 1841; and served as a judge of the Basel criminal court from 1842 to 1866. He has come to be identified with the thesis that a matriarchal state of society preceded the current patriarchal one, but his deeper and more original concern was not with systems of rule but rather with the cultural worldviews that they reflected.

In the debates concerning the Swiss Civil Code, Bachofen opposed the blanket imposition of the Code Napoleon and supported the approach that eventually incorporated more recognition of local custom into the Swiss code than into any other contemporary European system.

Maine argued for two main theses: that law evolved from status law to contract law and that the first form of organized society was “patriarchal.” As with Bachofen, Maine’s legal and ethnological activities were inseparable. His first major work, *Ancient Law*, was published in 1861, the same year as Bachofen’s *Mother-Right* was published. From 1863 to 1869 in India, Maine served as a legal member of the Council of India and as vice chancellor of the University of Calcutta.

Maine was the first British ethnologist to insist on the “comparative method” of historical investigation, although he did not make clear at first that he took it from Savigny. Contrary to Bachofen, Maine argued that the patriarchal system went back to the beginnings of the Indo-European language family. To specify it, he modified the Roman model only enough to incorporate points that he considered to be held in common with other ancient Indo-European legal systems, particularly Hindu law. The result was a social system in which the only organization was the household and literally all legal power resided in its eldest male. In this system, “law is the parent’s word.”

Eventually, in Maine’s view, as allowances were made for those among the descendants who would succeed to the position of the father, status within the

family and the society became more differentiated, increasing by slow degrees the rights of others within the family to delineate a portion of the property and act on their own regarding it. This eventually led to a system based on the individual power of contract, supported by a government detached from the family system.

Maine was a major proponent of legal codification, and no matter how debatable his movement from status to contract may have been as an historical thesis, there is no doubt that it described the thrust of British law in India.

Morgan was a year younger than Bachofen. He practiced law from 1844 in Rochester, New York, and served in the state legislature from 1861 to 1869.

Morgan was interested in general rules of development that covered all societies. His main works were the *League of the Iroquois* in 1851, *Systems of Consanguinity and Affinity of the Human Family* in 1871, and *Ancient Society* in 1877. He approached the ethnographic materials directly through Roman legal vocabulary and constitutional analysis. This included the concepts of consanguinity and affinity themselves. The result was to show how terminologies for kinsmen articulate with different forms of family organization and to thereby create an enduring and central concern of social anthropology. Equally important, however, he did not see primitive society as monolithic; for example, he recognized that the family system was not necessarily the same as the clan system, if any, which in turn was not necessarily the same system of government.

McLennan brought the arguments on matriarchy versus patriarchy together with another line of argument focusing on “totemism.” He was appointed parliamentary draftsman in 1871. His first major work was *Primitive Marriage*, published in 1865. He agreed with Morgan and Bachofen in holding that the first organized form of the family must have been based on the relation between mother and children, but he disagreed vigorously with most other aspects of their analyses. Basically, McLennan held that it was quite wrong to start with a small and sharply defined group such as the family in any form; what one had to imagine was the least fully conceptualized type of association. This was the undifferentiated territorial “horde.” He then held that the first and most basic rule required for the constitution of such a group was the rule of exogamy, that is, the rule that one had to marry outside of one’s own horde. He argued that

because there were still no principles that could order relations among hordes, this naturally led to the practice of marriage by capture.

McLennan saw evidence of marriage by capture in the marriage ceremonies of an extremely wide range of linguistic communities. He held that such ceremonies were more appropriate and reliable sources of evidence on the most ancient uses than were formal laws, particularly written laws, which must have arisen more recently. Thus, the ceremonies were not considered “mere” rituals or expressions of religious ideas alone. They were read as Savigny had read judicial proceedings, that is, as enactments of general societal relationships.

By the early 20th century, the lawyer-ethnologists were of little interest for two main reasons. The first was that, with the exception of Morgan, their social mechanisms assumed a time span for human history that turned out to be far too short. The second was that they came to be identified with the neo-Hegelians.

19th-Century Authoritarian Theory

The main authoritarian reaction to the theories based on republican conceptions was in two ideologies with roots in Hegel and St. Simon’s socialism: Auguste Comte’s positivism and Karl Marx’s communism. They agreed in seeing society as monolithic and hierarchical, rejecting pluralism as disorder and rejecting democracy as a delusion. Their main disagreement was over causality. Positivists argued that mind controlled matter, and Marxists argued that matter controlled mind. The legal positivism of John Austin (1790–1859) is parallel but separate, imperially grounded but not Hegelian.

The first anthropologist to espouse Comte’s positivism was E. B. Tylor (1832–1897). In 1889, Tylor’s *Primitive Culture* argued for “animism” as the first religion directly on the model of Comte’s “fetishism” and for Comte’s view of science as precluding recognition of human free will. The first legal scholars were the neo-Hegelians.

The Neo-Hegelians

The recognized founder of the neo-Hegelian school is Albert Herman Post (1839–1895). His publications, beginning in 1872, invoked Comte’s arguments and methods to attempt to construct a universal history of law and society. Unlike the lawyer-ethnologists, Post argued that evolution had a

definite goal, which was none other than the creation of a totalitarian world system. Joseph Köhler (1849–1919) was Post's successor and shifted the imagery from Comte to Hegel.

Köhler was a prodigious writer. The editor of the English translation of his *Lehrbuch der Rechtsphilosophy* (translated as *Philosophy of Law*) listed 48 major works up to 1903. The most important for anthropology is *Zur Urgeschichte der Ehe* [On the Prehistory of Marriage], published in 1897 and recently translated with a foreword by R. H. Barnes.

Köhler took totemism as the original and basic form of religion and social organization, citing James Frazer. This was considered to be a system of beliefs in which members of social groups, clans, or tribes are identified with distinct animal species or objects. Köhler argued that it followed that no one could belong to more than one clan because this "would result in a mixed animal." Given this, it further followed that the clan must always be based exclusively on either "mother-right" or "father-right."

Köhler argued the case with an analysis of kinship terminologies based on Morgan, noting that Morgan's glosses could be written out as equations. Thus, if the same term is applied to one's (ego's) father and father's brother, this is represented as Father = Father's Brother. Terminologies could then be compared as patterns of such equations.

Köhler interpreted all such equations as evidence of group marriage, meaning that all of the people from one clan married all of those from the other clan, even though Morgan had explicitly said otherwise. Nevertheless, Köhler concluded that it was irrefutable that "all peoples of the earth originally had group marriage" if we considered the derivation of group marriage from totemism and that "totemism presents itself to us in nearly all human activities, institutions, legends, [and] idioms as an ancient and later abandoned system."

Köhler's *Philosophy of Law* began with an "excursus" that deduced Köhler's position from a general definition of law and argued that, for humans, natural law is the law of culture, which it is "man's task" to create and develop. This "ideal of cultural development," in his view, would be served "if all states would unite in one great whole" through the formation of a "supranational" law. But he saw little hope that such a "world empire" and law would emerge by rational action of sovereign nations because it would result in a reduction of their jealously guarded

autonomy. therefore, Köhler held that war in pursuit of it was "valid."

French Sociology

Although Émile Durkheim (1858–1917) described himself as a republican, "republican" for Durkheim was not what it was for the Romans or Kant. Durkheim defined democracy only as a type of thought, not as any sort of organizational arrangement to ensure popular sovereignty. It was the widest extent of participation in "the governmental social consciousness," whereas "the role of the State . . . is not to express and sum up the unreflective thought of the mass of the people but [rather] to superimpose on this unreflective thought a more considered thought."

Durkheim's social analyses supported his politics. *On the Social Division of Labor*, his dissertation in philosophy, was intended to refute Adam Smith's description of orderly and efficient economic relations arising from the interactive exercise of personal judgment. Durkheim argued that the division of labor was social rather than individual. It was both mental and collective. Society was integrated by a principle of solidarity. The form of this solidarity evolved according to a necessary law of growth, drawn directly on the analogy of the biological evolution. It began with mechanical solidarity, where everyone literally looked, thought, and acted alike, and ran to organic solidarity, where people, behaviors, and roles were progressively differentiated and interlinked. People were drawn into these differentiated roles not by individual purpose or even the pressure of others but rather by an impulse for self-fulfillment because each alone was "incomplete."

Durkheim's interpretation of totemism drew on both Köhler and Tylor. Durkheim praised Köhler's analysis extensively in an important review published in *L'Année Sociologique* in 1897 and again in 1905. He then applied Köhler's argument nearly point for point, although without citing Köhler, to Baldwin Spencer and F. J. Gillen's representation of Australian totemism in *The Native Tribes of Central Australia* (1899). Spencer and Gillen, in turn, credited their theoretical perspective to Tylor. The result was *The Elementary Forms of the Religious Life*, first published in 1912 and then in English in 1915, widely considered one of the foundational works of modern sociology.

The argument began with the idea that categories of thought control our behavior. Durkheim then argued (paraphrasing Comte) that these categories,

being general and mental, cannot come from the individual but rather must come from society:

Man is double. . . . There are two beings in him: an individual being which has its foundations in the organism and whose activities are therefore strictly limited, and a social being which represents the highest reality in the intellectual and more order that we can know by observation—I mean society.

Durkheim's explanation of how the two beings come together is that the subjective dominates the objective, the general dominates the particular, and the state dominates individual experience and Köhler's idea of totemism. Hence, the categories were "born in religion and of religion."

Durkheim concluded with Köhler's argument that unity of the group is the basis for the self-identity of the individual: "We have shown how the religious force which animates the clan particularizes itself in particular consciousness." He also argued, following both Hegel and Köhler, that only the group is active, not individuals:

The collective consciousness is the highest form of the psychic life, since it is the consciousness of the consciousness. Being placed outside of and above individual and local contingencies, it sees things only in their permanent and essential aspects, which it crystallizes into communicable ideas.

The "two beings" argument was repeated in *Mental Functions in Inferior Societies* by Durkheim's colleague, Lucien Lévy-Bruhl, in 1910. Others proposed different ideas of the original form of society or its essential basis but kept the same basic idea that there was some such elemental form or essential basis and the same circular methods of arguing for it.

German Sociology

French sociology and the contemporaneous German sociology of Georg Simmel (1858–1918), Ferdinand Tönnies (1855–1936), and Max Weber (1864–1920) agreed that society was unitary and that human free will and choice were illusions. The differences were only in the ways in which they focused their arguments. They were less interested in primitive religion and early societies than in contemporary religion and modern society. Rural life was characterized

as traditional and superstitious, emphasizing the group over the individual. Urban or civilized life and thought were rational, scientific, and individualistic. Simmel's sociology of religion was simply the claim that religion was society, that is, that social determinism was religious determinism. The most general difference between Tönnies's and Weber's arguments was that Weber's argument was built around the dichotomy between form and substance, whereas Tönnies's argument stressed the dichotomy between will and reason. Tönnies's *Gemeinschaft* and *Gesellschaft* were forms of collective will. Weber, like Comte, took thought as the basis of action and equated the evolution of society with the evolution of rationality.

Weber had studied law at Heidelberg, Berlin, and Göttingen and had written his dissertation on medieval commercial law in 1894. The connection between the economy and law was the central theme of his massive *Wirtschaft und Gesellschaft* (Economy and Society), published in 1922. This aimed directly at rejecting Smith's view that division of labor is the product of efficiency-seeking behavior at the individual level. Instead, Weber portrayed law as developing by an internal logic of increasing formality and rationality.

Weber's stages of legal development followed Comte's and similarly implied that legal values descend from and are consonant with religious values. First was primitive law with "magically conditioned formalism," evoking Comte's fetishism. This coalesced into Old Testament religion for Comte and Old Testament law for Weber, that is, charismatic revelation by law prophets. Next was "cautelary jurisprudence," which seemed to refer to the pragmatic law finding of the Roman Republic. "Imposition of law by secular and theocratic powers" was next and suggested the imperial and papal rationales, again agreeing with Comte, and "rational" law corresponded directly with Comte's positivistic science, being based on generalization by rational bureaucrats from specific cases to principles according to universal logical rules.

The problem is that modern European law has no more developed out of ancient Judaism than has modern science. Nor did Roman imperial law supersede Roman republican law, as Savigny showed. But succession was what Weber wanted because succession suggests hierarchy, and hierarchy was the unifying theme of his argument.

Pragmatism in Law

The American counterpart to European post-Kantian empiricism is pragmatism. Pragmatism grew out of the discussions of the “Metaphysical Club” that met in Cambridge, England, during the early 1870s. Especially important pragmatists at that time included Oliver Wendell Holmes, Jr., Charles Peirce, and William James and later included John Dewey, G. H. Mead, and W. I. Thomas. In pragmatic legal theory, “law” is firmly focused on courts and what they do.

Pragmatism uses an empirical theory of knowledge and meaning to bring together the entire panoply of post-Kantian empirical developments from physiological psychology, to developmental and social psychology, to a theory of social relations, and finally to an understanding of key institutions—most notably law, education, and economics. Pragmatic legal thought was continuous with the continental jurisprudence descending from Savigny.

Holmes’s most important and expansive work was *The Common Law* (1881). The historical sweep covered the XII Tables, the law of the Germanic tribes, English common law, and modern American case law. It was not a codification but rather a delineation of basic legal concepts as illustrated by cases. The introduction focused on the general concept of liability, which became Holmes’s touchstone for differentiating criminal law from torts and contracts. Holmes argued that for criminal law tort the idea of liability, based on an idea of revenge, is “of the first importance,” although in contract law it is “hardly material” outside a limited number of cases. The concepts of liability differ, however, between criminal law and tort and are linked to differing interpretations of other concepts such as trespass, malice, reasonable, foreseeable, accident, intent, and responsible.

One of Holmes’s most important underlying ideas was that in each of the major branches of law, the basic categories under which the cases and exegeses are grouped form, in themselves, an evolved philosophy of law, a repository of experience, ordered and retained in an evolved and evolving social system.

Benjamin Cardozo (1870–1938) demonstrated the agreement between Ehrlich and Holmes in a series of lectures delivered at Yale University and published in 1921 as *The Nature of the Judicial Process*. His focus, like Holmes’s focus, was on how judges decide cases, particularly difficult cases. This, he argued, had led to increasing recognition of the

necessity for the sociological method in Ehrlich’s sense. A quotation Cardozo took from Dean Pound was particularly apt and indicated nicely the broad agreement among all four:

It is true, I think, today in every department of the law that the social value of a rule has become a test of growing power and importance. This truth is powerfully driven home to the lawyers of this country in the writings of Dean Pound[:] “Perhaps the most significant advance in the modern science of law is the change from the analytical to the functional attitude.” . . . “The emphasis has changed from the content of the precept and the existence of the remedy to the effect of the precept in action and the availability and efficiency of the remedy to attain the ends for which the precept was devised.”

Pound’s position in this stream is clear from the same quote. Law is a set of social tools that answer to diverse purposes in diverse ways. Conversely, social life itself defines diverse purposes for individuals to pursue.

Pragmatism in Anthropology to 1950

Although Franz Boas (1858–1942) and Bronislaw Malinowski (1884–1942) are equally identifiable with the intellectual traditions of pragmatism, Boas’s interests did not lead him to encounter issues law.

Bronislaw Malinowski

Malinowski initially took his D.Sc. in physics at Kraków in 1908, but he decided to go into anthropology instead. His first step was to take courses from Wilhelm Wundt and Karl Bucher at Leipzig. Wundt was concerned with the relation of mind to action, and Bucher was concerned with the organization of work. In 1910, Malinowski became a postdoctoral student at the London School of Economics, planning to do research in the South Pacific. He studied mainly under Charles Seligman (1875–1940) but also associated with Edward Westermarck, Leonard Hobhouse, W. H. R. Rivers, and A. C. Haddon, among others. The theoretical assumptions and issues at the London school were essentially the same as at Leipzig. They shared a central concern with the emergence of human mentality and human culture out of a pan-human physiological substrate and the way in which human thought was shaped by culture, and

ethnological fieldwork was well established as an extension of laboratory methods in Wundt's sense.

Malinowski left for the Trobriand Islands in 1914 and remained there until 1918, formally interned as an enemy alien. He is recognized as having developed what is now called "participant observation" and also was the inventor of the ethnographic monograph as we now know it. This is not a reconstruction of a past condition or a pristine "precontact" society but rather a description of a community as it is observed with the investigator located within it.

Malinowski's Trobriand monographs were pluralistic and relativistic. Each took a group of theories reflecting one of our institutions and held it up against their uses. Thus, *Argonauts of the Western Pacific* in 1922 compared conventional economic concepts of rationality, markets, money, and value with the Trobriand system of overseas trade, called the *kula*. *Sex and Repression in Savage Society* in 1927 tested and rejected Freud's concept of the Oedipus complex. *Crime and Custom in Savage Society* in 1926 did the same for neo-Hegelian conceptions of law and custom and is Malinowski's main work on law.

Although Malinowski was absolute in his rejection of the neo-Hegelians, he did not discuss their opponents. Yet his conception of the sanctioned basis of custom was very similar to Ehrlich's conception of the living law, and his idea of when sanctioned intervention was required paralleled that of Ehrlich and Jhering, as was subsequently recognized by Cardozo and Pound.

Karl Llewellyn

Karl Llewellyn (1893–1962) is the legal scholar who most ethnologists are likely to have read. The specific work they are most likely to have read is *The Cheyenne Way*, written mainly by Llewellyn using fieldwork by E. A. Hoebel. This began with a discussion of the method according to which the cases were collected. They were texts rather than actual observed events, but they were of a specific sort calculated to illustrate basic principles of law; they were "trouble cases." Trouble cases are cases that present general problems for the group as a whole and that are remembered for those problems and their solutions. The book presented the cases under subject headings according to the types of problems and remedies they illustrate and concluded with three chapters on "law-jobs and juristic methods" that presented Llewellyn's theory of law. Although it clearly belongs

to Savigny's tradition, it does not take any established analysis within that tradition as a starting point. It is of a piece—a simple, striking, and new view of the way in which law arises from the life of the people.

Positivism in Anthropology to the Present

The period between around 1930 and 1960 saw a major intellectual swing from pragmatism and empiricism to positivism. Roughly in chronological order, the main arguments fall into four main clusters: an initial isolated "theoretical" statement by A. R. Radcliffe-Brown (1881–1955), the "cultural" view of E. A. Hoebel (1925–1983), a long series of arguments aimed at treating law as "dispute settlement" that is shaped or controlled by the larger social structure, and a debate on the general definition of law. The end result was theoretical sterility and isolation.

A. R. Radcliffe-Brown

Radcliffe-Brown was a forceful proponent of the positivism of Henri Hubert and Durkheim, and he wrote the section on primitive law in the general article on law for the 1934 *Encyclopedia of the Social Sciences*. The article began by dismissing the entire line of scholarship from Savigny to Pound as irrelevant to the subject. The reason was that the jurists defined law as involving "organized legal sanctions," and primitive societies did not have any; rather, they had sanctions imposed by society itself. Deeds that offended the "moral sense of the community" would be subject to three sanctions: a general diffuse sanction that subjects a person to general disapproval, a ritual sanction that puts a person in a condition of ritual uncleanness, or a penal sanction "whereby the community through certain persons acting as its constituted judicial authorities inflicts punishment."

Although few subsequent writers have agreed that primitive society had no law, virtually all have recognized that the perspective of the great jurists was incompatible with positivistic social determinism.

E. A. Hoebel

Hoebel was a student of Boas. Hoebel was interested in Comanche law but was having trouble conceptualizing it. Boas asked Llewellyn to meet with him. The two worked together on *The Cheyenne Way*. Hoebel then continued on his own, moving from Llewellyn's pragmatic conception of "law jobs" to his own conception of a jural code of postulates and corollaries.

For the Ifugao of the Philippines, Hoebel listed 6 postulates and 17 corollaries. The list included entirely unrelated ideas, most of which were in legal terms clearly not adjudicable or enforceable. The first, for example, was as follows: "The bilateral kinship group is the primary social and legal unit, consisting of the dead, the living, and the yet unborn." The second was as follows: "Supernatural forces control most activities, and the actions of human beings are either compatible or incompatible with the predilections of the supernaturals," a corollary of which was the necessity of headhunting.

Hoebel's claim was that all such beliefs form a unitary controlling whole, which he characterized as "superorganic." If it were true, the Ifugao would be a community of gullible rule followers with no sense of logical inconsistency or incoherence. In actuality, most of these ideas are not rules of behavior at all.

Dispute Settlement

The effort to treat law as socially structured dispute settlement runs from Max Gluckman, to Elizabeth Colson, to Laura Nader. The core ideas of the dispute are well represented in *The Disputing Process*, published by Nader and Harry Todd in 1978.

Gluckman is known mainly for his "structural-functional" explanation of conflict, but he was also very forceful in urging a complete theoretical separation of anthropological theory and jurisprudence. The argument equated the increasing power of a science with the development of specialized and distinct scientific vocabularies. Because anthropology was a new and separate discipline with its own purpose, anthropologists who used legal concepts had to give them new and separate meanings. The purpose of anthropological theory was to show that the ideas and behaviors of people were directly shaped by the organization of their society. However, although legal theory and anthropological theory were separate, anthropologists should borrow whatever descriptive insight they could.

In *The Judicial Process Among the Barotse of Northern Rhodesia* in 1955, Gluckman showed that Barotse judges arrived at their decisions using the same methods described for Western judges by Cardozo. Gluckman observed the way in which specific cases were handled and followed them from the point of view of their prejudicial status and origin, the way in which they were recast for adjudication, and the vocabulary of legal debate that was applied.

He saw Barotse rules of law as clear counterparts of judicial conceptions of rational behavior in tort and civil law. But none of this descriptive apparatus, for Gluckman, was "theory." Rather, theory was a further idea he offered to explain it. This was the distinction between societies that are "multiplex" and those that are differentiated. Where relationships are multiplex, dispute settlement is readily available and produces solutions that are intended to maintain social ties. Where relationships are specialized and differentiated (not multiplex), dispute settlement is impersonal and often difficult to reach, and it aims at settlements based on individualistic ideas of justice or equity.

One problem with this is that it does not really explain what seems to need an explanation the most: why Cardozo's analysis actually fits. Another is that it sets up a contrast between types of "societies" that makes no sense. Is a village a society or a nation? Is a household a society? In American families, for example, one person deals with the same others on many bases. In American commerce, one person usually deals with others only in highly specialized roles. So, is American society multiplex or differentiated? "Multiplex" may be a reasonably clear idea, but "society" (among others) is not.

Colson and her students recognized the paradoxes and thought that Gluckman's characterization was too sharply polarized. They turned to what they considered a "processual" model of organization that, according to Nader and Todd, "focusses on people enmeshed in networks of social relations, on people making decisions that are based on a number of competing factors." This, however, was harder to reconcile with the idea of social unity and ultimately led to a still further retreat that focused only on disputes and put off the social theory for later.

In their preface to the 1978 book, Nader and Todd described the project as having begun with the program set out in her 1965 review of the anthropology of law, resting on four assumptions:

- (1) There is limited range of dispute within any particular society; (2) a limited number of formal public procedures are used by human societies in the prevention or handling of grievances . . . ; (3) the disputants have a choice in the number and modes of settlement . . . ; [and] (4) the range of manifest and latent functions of law vary cross-culturally. We were interested in understanding the conditions that defined the presence and use of specific

dispute-resolving procedures. We would concentrate on one function of law—the management of disputes. Because the modes of settlement are limited in number, dispute processes would offer a good starting place for comparison.

There was no longer any claim about society in general or even law in general, only “comparison” as a distant goal for no clear purpose. The debate died out during the 1980s.

The Definition of Law

The debate over the definition of law was similar. Central figures were Gluckman, Paul Bohannan, and Leopold Pospisil. Bohannan, following Kantorowicz, argued that law could be defined in its own terms and understood in those terms. There was no need to impose anything on it from the outside. Pospisil and Gluckman disagreed, holding that law had to be defined anthropologically. They disagreed with each other, however, over how to do this. Gluckman argued for separating the anthropology of law from legal studies so as to combine it with social theory. Pospisil held that the purpose was to make cross-cultural comparisons of legal systems as such.

Pospisil's first major work, in 1958, was *Kapauku Papuans and Their Law*. Kapauku legal decisions were rendered mainly by “big men,” that is, local informal leaders. Pospisil's analytic headings drew on Roman law, and the conclusion gave four general attributes of the legal process with evident Roman roots: authority, intention of universal application, *obligatio* (imposition of an authority external to the dispute itself), and sanction. In 1971, his *Anthropology of Law* began with a review of legal theory making it clear that his own theoretical touchstone was Ehrlich. But where Ehrlich insisted on framing legal theory within a general theory of social organization, Pospisil simply said that his concern was with legal decisions alone and offered the definition from his Kapauku analysis. The rest of the argument compared this definition with those of a series of other writers. This brought him to his disagreement with Bohannan.

Bohannan reflected the same jurisprudential tradition but accepted its pragmatic methodological assumptions. Pospisil focused on a distinction that Bohannan had used in 1957 in *Justice and Judgment Among the Tiv* between the folk system of law and the analyst's system imposed from without. Pospisil commended the distinction but criticized Bohannan

for concentrating only on the folk system, saying that although Bohannan clearly presented a description of the Tiv conceptualizations, it lacked “broader theoretical considerations” that Pospisil equated with “analytical systems.” From Bohannan's own perspective, however, the broader considerations arose from the description itself, and the analytic systems that Pospisil was demanding would only have obscured them.

In a 1994 review of legal anthropology in Britain, Chris Fuller cited this debate as a reason for a broad loss of interest among nonspecialists during the 1980s.

Return to Pragmatism

In 1974, the Association for Social Anthropology in Britain published the papers of a conference at Keele University that returned to the pragmatic perspective. Contributors were Lloyd Fallers, P. H. Gulliver, J. L. Comaroff and Simon Roberts, F. G. Snyder, Sally Falk Moore, and J. A. G. Perry. Only Fallers came close to offering a definition of law, but this was just as “our own” idea that could serve as a template. Gulliver described mediation in general terms, but again not with the aim of proposing a cross-cultural definition. The other papers were aimed still more directly at explaining forms of adjudication entirely in local terms while at least implying that external definitions of law or of the determinants of behavior are not required and do not help.

The concluding paper was by Moore, originally a student of Llewellyn and both a lawyer and an anthropologist. Moore argued that legal systems were ordered from within and could be seen from within. Interests affect outcomes, but interests cannot be determined in advance or by external criteria. They are themselves socially constituted, built up or altered even in the course of reaching the decisions they affect. They exist at many levels and are entangled with matters such as friendship and personal resentment, which they sometimes support and sometimes contradict. They are part of the fabric of life, but the way they are built up is recognizable with no need for prior “scientific” definitions.

During the past 10 years or so, approaches to law and society in anthropology have largely returned to the interest-oriented, constructivist, empirical, and bottom-up perspective of the republican tradition of legal scholarship represented by Moore for reasons that have little to do with the previous 20 years of positivistic

argument and a great deal to do with changes in other fields and in the world at large.

Increasingly, social scientists and lawyers have come to work much more cooperatively with each other and in terms that spring from law as understood from the republican perspective. This has been especially visible in meetings and publications of the Law and Society Association (founded in 1964), which has provided an important common forum for sociologists, anthropologists, lawyers, and others interested in what has come to be called “sociolegal studies.” In consequence, most younger sociologists have rejected the strident antilaw perspective and social determinism that was common in sociology during the 1960s and have moved much closer to the empirical, and mainly pragmatic, perspective that anthropologists have held to more or less consistency despite the positivist excursion. Virtually no sociologist or anthropologist interested in law now dismisses legal scholarship by lawyers as merely normative or takes as his or her mission to “explain” law in the sense of denying its independent reality or importance. As represented by one recent collection of readings by Moore in 2005 and another by the sociologist Alfonso Morales in 2003, what we now see are many more joint or cooperative projects on topics of mutual interest, from development and globalization to how to do ethnographic fieldwork. Social scientists do not yet quite recognize writers such as Holmes, Jhering, and Ehrlich as social theorists as well as legal theorists, but anthropologists, sociologists, and pragmatically oriented lawyers (who are the mainstream) increasingly have the same theoretical priorities and address common concerns in mutually intelligible ways.

LAZARET CAVE

Lazaret Cave (*Grotte du Lazaret*) is a pre-Neandertal cave occupation site located on the French Mediterranean coast in Nice (Alpes-Maritimes) on the western slope of Mount Boron. This karstic cave is extremely large, measuring 40 meters long by 15 meters wide with a ceiling 15 meters high. Excavations conducted by François Octobon and Henry de Lumley have produced a rich archaeological assemblage as well as 10 fragmentary hominid specimens. The archaeological material derives from stratigraphic complex C and is subdivided into three main units, which are further subdivided into distinct archaeological stratigraphic units. Combined uranium/thorium (U/Th) and electron spin resonance (ESR) dating of faunal materials associated with the complex C layers indicate a late Riss occupation corresponding to Oxygen Isotope Stage 6 (OIS 6). The site is notable for its evidence for the existence of structures built inside the cave by its occupants.

The hominid material from the site is limited to very fragmentary remains and isolated teeth provisionally typed to pre-Neandertals by Marie-Antoinette de Lumley, a conclusion borne out by subsequent dating. The most significant hominid material from Lazaret is a complete parietal belonging to a juvenile who was approximately 9 years of age. This individual shows pathological development and vault thinning that were likely due to a bone infection, resulting in death; alternatively, the pathology has been described as the result of a tumor pushing the meninges into the parietal, resulting in bone resorption.

The archaeological and faunal material from the site reflects long-term occupation by pre-Neandertals. Units C1 and CII contain Acheulean lithic assemblages with a large makeup of bifaces. U/Th and ESR dates from red deer enamel indicate an age of approximately 170,000 ($\pm$ 20,000) years for Unit CII. Unit CIII contains a Mousterian lithic assemblage derived from the Acheulean with many flake tools lacking bifaces, and U/Th and ESR dates from red deer enamel indicate an age of approximately 130,000 ($\pm$ 15,000) years. These dates place Lazaret squarely in the pre-Würm OIS 6 stage. Taphonomic analysis of the faunal material recovered indicates alternating stages of habitation between humans and carnivores, primarily wolves (*Canis lupus*).

Prey species recovered from the site are predominantly goats (*Capra ibex*) and red deer (*Cervus elephus*), with limited equid and bovid material. The age/death profiles of the goats and deer are indicative of selective hunting, and bone modifications associated with all stages of carcass processing are present. The equid and bovid remains are represented by only some parts of the skeleton lacking any carnivore gnawing marks, supporting the contention of selective transport of specific parts of these larger animals, whereas the entire carcasses of smaller prey mammals were transported to the site. Although the presence of some gnawed bones and coprolites indicates carnivore occupation of the cave, the majority of the prey fauna collection and transportation can be confidently ascribed to the hominid occupants.

Perhaps the most interesting feature of the Lazaret site is the construction of a wall or hut within the cave, presumably used either to separate an intensely used portion from the rest of the large cave or to create shelter from weather. Features thought to be post-holes surrounded by rock features are indicative of the construction of these huts or walls within the cave. On the basis of the distribution of archaeological material, de Lumley argued for the presence of entrances and internal compartments constructed via these walls. Tiny seashells that may have been brought into the site attached to seaweed, as well as mammalian foot bones (presumably attached to hides), are found within the smaller compartments surrounding a hearth, and de Lumley presented this material as evidence for bedding.

Although the most complex behaviors arguably present at the site are primarily speculative, the presence of some sort of structure within the cave is well

established. The long-term occupation of the site and its use as a central place to process carcasses procured via selective hunting are also well established, marking Lazaret as an important site for understanding the lifeways of pre-Neandertals within the Middle Paleolithic.

LEAKEY, LOUIS S. B. (1903–1972)

The English anthropologist Louis Leakey was known primarily for his discovery of *Proconsul africanus*, his interpretation of *Zinjanthropus*, his announcing the discovery of *Homo habilis*, and his great influence on primatology. Born in 1903 at Kabete Mission, Kenya, Leakey benefited from two distinct cultures: the English culture that was provided by his parents, Harry and Mary Leakey, and the Kikuyu tribe culture to which he was initiated at 13 years of age. Acculturated into tribal lore, Leakey acquired the ability to survive in the bush. Other than a brief time in England at Gorse Cliff school during 1912 and 1913, his formal education during the period from 1913 to 1919 was provided by tutors from England. Regarded by the tribe as more African than European, Leakey was known as the black man with the white face. During his youth, his interests in the past and the collection of artifacts began to develop. With the aid of the curator of the Kenyan Museum, valuable insights stimulated the young naturalist's mind. This influence continued until he returned to England after World War I.

After completing his formal education at Weymouth College, Leakey entered St. John's College in Cambridge in 1922. Interested in modern language, his term was suddenly interrupted by a rugby accident in 1923. This accident allowed him to have the invaluable experience of participating as a member of the British Museum East Africa Expedition in the Tanganyika Territory. Under the leadership of the Canadian paleontologist W. E. Cutler, Leakey learned the finer points concerning the handling of fossils and site managerial skills. After the year of expedition, Leakey returned to England to complete his language requirements and to take archaeology and anthropology in 1926. Besides multiple expeditions to East Africa, Leakey held a fellowship (1929–1934), was a Leverhulme Research Fellow (1933–1935), and was the Munro Lecturer at Edinburgh University (1936). Furthermore, he was the Herbert Spencer Lecturer at Oxford (1961), the Regent's Lecturer at the University of California, Berkeley (1963), and the Silliman Lecturer at Yale University (1963–1964). Leakey was awarded multiple honorary doctorates. He also holds an honorary doctorate of science from Oxford University and the University of East Africa and holds a doctorate of law from the University of California, Berkeley, and Guelph University.

Throughout his career, Leakey published many articles and books, most notably *Stone Age Africa* in 1936, *Adam's Ancestors* in 1960, and *Olduvia Gorge* in 1965. Concerned with both African life (he became a citizen of Kenya in 1963) and natural history, Leakey was a founder trustee of the Kenya National Parks and a trustee of the East African Wildlife Society. Furthermore, he was the honorary curator for the National Museums of Kenya, whereby he created and served on the Pan-African Congresses on Prehistory and Pleistocene Studies.

Leakey's contribution to anthropology is great; however, the basis for his success can be seen in the teamwork with his spouse. Although his first marriage to Henrietta Wilfrida Avern ended, his second marriage to Mary Douglas Nicol, an archaeologist, was a beneficial and integral part of this team's anthropological dynamics. Among his various academic and scholastic functions and duties, including parental duties, Leakey was interested in humans' closest living relatives—the primates. He influenced the area of primatology. He helped secure the future for Jane Goodall's work with the chimpanzees, Dian Fossey's study of the mountain gorillas, and Biruté Galdikas's work with the orangutans.

Although Leakey was viewed as always good-natured, the stress and workload began to undermine his health. After collapsing on four different occasions for four different reasons, Leakey died of a heart attack in London's St. Stephen's Hospital in 1972. Although some scientists considered some of his interpretations of the archaeological evidence as being hasty and erroneous, his dynamic personality and naturalistic inquiry benefited anthropology in the understanding of the deep history and descent of the human species. Supporting Charles Darwin's (1809–1882) belief that Africa was the cradle of human evolution, Leakey was concerned with the complete array of African history, from humans' remote hominid ancestors to modern-day life. Leakey's naturalism and life history illustrate the commitment to both science and humanity.

Contributions and Perspectives

Prior to the discoveries at Olduvia Gorge, questions pertaining to the origin of the human species were

surrounded by controversial speculation. Believing that Darwin was correct in his speculation that Africa, as opposed to Asia, was the cradle of humankind, Leakey's speculation was confirmed by a hominid find by Hans Reck in the area known as Olduvai Gorge. Beds that are exposed by the natural formation yielded many answers concerning both the geological and historical aspects of the natural evolution of the human species. It is this point, including the behavioral patterns of today's primates, that led Louis and Mary Leakey on the road to discovery.

Although Leakey previously discovered a skull he called *Proconsul africanus* (estimated at 20 million years old), the greater find that would be associated with the Leakeys came through the efforts of Mary Leakey. At Olduvai in 1959, she discovered a skull that differed from that of any known hominid. Exhibiting larger teeth and pronounced bone structure, Louis Leakey named this robust form *Zinjanthropus* (estimated at 1.75 million years old), and it is commonly known today as *Australopithecus boisei*. Although Mary Leakey made the first significant find, Louis Leakey would make the second discovery himself.

During an excavation in 1960, Leakey recovered a hand, clavicle, and foot that belonged to a new hominid form. Because of its means of locomotion and stone tools (Oldowan culture), Leakey named this new form *Homo habilis* (estimated at 2 million years old). According to the new discovery, including further discoveries not attributed to Leakey, *H. habilis* had the structure of the lower extremities that indicates bipedality, a rounded cranium with a cranial capacity ranging from 600 to 750 cubic centimeters, a decrease in dentition (molars and premolars), and an increase in stature. Similar discoveries with slight differing morphological features (for example, smaller occipitals, no brow ridges) are attributed to *H. habilis*'s contemporary, named *Homo rudolfensis*. Thus, the phylogeny of the human species became the following. *Australopithecus afarensis* shares a common ancestor. *A. afarensis* from Hadar and Laetoli leads to *H. habilis* on one side, and *A. afarensis* from Hadar leads to *A. africanus*, and then *A. Boisei*, on the other side.

Although Leakey was known for his controversial, and sometimes premature, explanations concerning the evidence, his dedication in search of human origins is unquestionable. Concerned with Africa's past and future, Leakey was able to further paleoanthropology and conservation for current wildlife. He

believed that Darwin was correct that Africa was the cradle of human evolution. Consequently, the evidence recovered by Leakey (both his wife's discovery and his own) supports Darwin's speculation. Furthermore, the antiquity of the human species and its cultural influences could be reassessed due to Leakey's discoveries. Through fund-raising and organizational efforts, he increased awareness of human evolution and primate studies. Leakey's contributions, although not all scientific, greatly benefited the discipline of anthropology.

LOUIS S. B. LEAKEY

Louis Leakey was born in Kenya on August 7, 1903, the son of British missionaries (Anglican Church) serving the Kikuyu tribe. Being the first white baby born among the Kikuyu, he was brought up in a bicultural experience that made him a member of the tribe and an expert on their language and

culture. While a child in Kenya, Leakey found fossils and arrowheads that stimulated his interest in paleontology.

In 1924, Leakey took a leave of absence from his studies at Cambridge University to heal from a rugby injury. He joined an archaeological expedition and then led four other archaeological expeditions for fossils in Africa over the next decade. In 1936, Leakey married Mary Nicol, who would become his partner on African fossil expeditions and who would make important scientific contributions herself. The couple had three children: Jonathan, Richard, and Philip.

In 1948, Leakey found the skull of a Miocene hominoid to which he gave the scientific name *Proconsul africanus*. After study, he concluded that the skull was from an ape-like creature that had lived between 23 and 14 million years ago and that it may have been a common ancestor to humans and apes. During the 1950s, Leakey dug for fossils in the Olduvai Gorge in Tanzania. He discovered what he identified as human remains and the bones of more than 100 different extinct animals. The first important discovery at Olduvai, which Louis named *Zinjanthropus boisei*, was uncovered by Mary Leakey on July 17, 1959. Now known as *Australopithecus boisei*, the find was a landmark in paleontology.

Leakey's legacy includes another find in 1960 that eventually led him and his team to announce the new species *Homo habilis* or "handy man." Leakey believed that this species was a direct human ancestor. The African fossils discovered by Leakey generated numerous questions. What was not questioned is that Leakey made significant contributions to knowledge about the origin of humans.

Leakey died in 1972. During his lifetime, Leakey made many important contributions to anthropology. He was influential in relocating the search for the origin of man from Asia to Africa. The Olduvai Gorge fossils added several branches to the human genealogical tree. He influenced and assisted researchers in many related fields. He inspired Jane Goodall, Dian Fossey, and Biruté Galdikas to do field studies of chimpanzees, mountain gorillas, and orangutans, respectively.

OLDUVAI GORGE

Olduvai Gorge, located in northern Tanzania, has revealed many secrets about early humans. The 30-mile-long ravine with its steep 295-foot-high sides contains layer after layer of fossils, built up over the last two million years. The lowest layers are about two million years old, making it possible to date the fossils discovered in each layer. Layers of fossils alternate with layers of volcanic ash, which has preserved plant and animal life.

Probably the world's best-known fossil site, Olduvai Gorge was first discovered in 1911 by German entomologist Professor Wilhelm Kattwinkel when he fell down a ravine while chasing a rare butterfly. He realized that the fossil beds surrounding him were a great anthropological find. Significant finds at the site include animal fossils, hominid specimens, and crude but functional stone tools. Nearby are the ruins of an ancient city.

Dr. Louis Leakey and his wife, Mary, did an extensive study of the site, beginning in 1931 and continuing for more than three decades. In 1959, Mary Leakey found a nearly complete human skull. Because of its heavy build and thick bones, it was determined that it represented a robust species to which scientists gave the name *Zinjanthropus boisei*. They soon began calling the man Zinj. He was also known as the Nutcracker Man because of his enormous back teeth. Zinj was one of the first hominids to undergo radiodating, which showed the skull to be 1.8 million years old.

In the 1960s, the Leakeys found the remains of a 1.4-million-year-old man known as *Homo habilis*. Unlike Zinj, *Homo habilis* had a lighter build. After

studying the bones from the hand of *Homo habilis*, scientists concluded that the opposable thumb would make him capable of carving the stone tools found at Olduvai Gorge.

In the 1970s and 1980s, Mary Leakey discovered footprints and fossils of 3.6-million-year-old hominids. The Leakey's son, Richard, was also involved, and he located another example of *Homo habilis*. The legacy of Olduvai Gorge lies in its variety and large number of finds, including fossils of 150 animals, bones of two different types of hominids, and hundreds of tools.

LEAKEY, MARY D. (1913–1996)

Some academicians may believe that only one who has had extensive formal training in a profession can make a substantial contribution to it. However, the numerous and important achievements of Mary D. Leakey invalidate this view because she never obtained a formal degree in her area of specialty, although she did

receive a number of honorary degrees. Her work is primarily in the area of archaeology, but it is of obvious value to anthropologists.

Mary Leakey was born in England on February 6, 1913. Her father was a landscape artist who died early in her life. Yet Mary was able to spend much of her youth traveling in Europe. In fact, at 11 years of age, she had the opportunity to visit a famous cave in France, and it apparently increased her interest in anthropology. In 1930, she had some exposure to a university education by auditing courses in archeology and geology, but she left the university without receiving a degree.

Mary Leakey did, however, continue her interest in archaeology and apparently had an admirable ability to illustrate and record what was found in various excavating sites where she was a participant. She also developed an expertise concerning stone tools. In addition, Leakey is credited with a number of important discoveries that occurred in 1959 and 1975 and during the late 1970s. All of them constitute a

contribution, but the one made during the late 1970s related to footprints demonstrating that a human had been walking upright a very long time ago. This particular finding resulted in changes in theories concerning the evolution of the human species in terms of walking.

The discoveries of Mary Leakey during these years are especially important because they give us some idea as to what the past was like in terms of human evolution. Yet besides these valuable discoveries, she should also be recognized for calling our attention to the value of recording and describing the artifacts that we uncover from the earth. She also found time in 1984 to write an interesting biography titled *Disclosing the Past*. Leakey continued her professional interests in retirement but died in 1996 at 83 years of age.

MARY D. LEAKEY

Mary Douglas Leakey was a leading paleoanthropologist, anthropologist, scientist, and writer. She was born in London in 1913, the daughter of a popular landscape painter, Erskine Nicol, and Cecilia Frere. During her parents' frequent trips to France, she gained an interest in the art of the French caves of Font de Gaume and La Mouthe. She was also able to help with

archaeological digs, where she found prehistoric stone tools.

After her father died in 1926, Mary returned to London with her mother. By the time Mary was 20 years of age, she had worked on archaeological digs in England as both an excavator and an artist who made drawings of the finds. Her artistic abilities captured the attention of Louis S. B. Leakey, then a Cambridge University professor. After working together with Mary on archaeological projects, Louis Leakey eventually divorced his wife in 1934 and married Mary in 1936.

In 1935, Mary and Louis Leakey visited the Olduvai Gorge in Tanzania, where in 1948 Mary discovered *Proconsul africanus*. In 1959, she discovered *Zinjanthropus boisei*, which is now called *Australopithecus boisei*. In 1960, she found *Homo habilis*.

Louis Leakey died in 1972, and after his death Mary carried on their work. She conducted lecture tours around the world and continued to make important fossil finds in the Olduvai Gorge. She often worked with the couple's son Richard Leakey, who made important advances in anthropology on his own.

In Laetoli, Tanzania, in 1979, Leakey discovered a series of 89 fossilized hominoid footprints estimated to be 3.5 million years old. It was a major fossil find.

Among Leakey's writings dealing with early human fossils was *Olduvai Gorge: My Search for Early Man* in 1979. She also contributed to the archaeology of the Stone Age with research on Tanzanian rock art (*Africa's Vanishing Art: The Rock Paintings of Tanzania*) in 1983. Her 1984 book, *Disclosing the Past: An Autobiography*, tells of her first visit to the Olduvai Gorge.

In 1983, Leakey retired from fieldwork. However, she continued to write scientific articles for years afterward. She died in 1996.

Leakey made many contributions to paleoanthropology. Probably her two most important contributions were the refocusing of attention on human origins from Asia to Africa (with Louis Leakey) and the great increase in sophistication she applied to the science through a multidisciplinary approach.

LEAKEY, MEAVE EPPS (1942–)

Meave Leakey seems to have the philosophy that if we can understand our past, we should be in a better position to understand our future. Such a view might not be the only reason for looking backward for what we can find out about ourselves today, but most would agree that it is a good one. She has practiced her philosophy by becoming one of the most renowned paleoanthropologists of this day.

Leakey's professionalism should not be too much of a surprise considering her background. She comes from a family that has had a distinguished reputation for digging out the facts that help to explain human evolution. The efforts of her family paid off handsomely due to their numerous and important findings. She has followed in the family tradition with her own professional accomplishments, and evidence suggests that she could make additional ones in the future.

Leakey received her B.S. in zoology and her Ph.D. in zoology and marine zoology from the University of North Wales. In 1968, she worked with Richard Leakey when he was conducting his research near a lake in Kenya, and the experience provided her with

the opportunity to engage in beneficial research activities. Certainly one of her most notable professional accomplishments occurred in 1999, when her research team found a skull and jaw suggesting that there had been a newly discovered branch of an early human family. It also suggested that there existed in the past a type of species of which present-day researchers were unaware. Her discovery also contradicted the current view at the time, namely that humans evolved from just one branch. This important finding understandably brought her national and international attention and contributed greatly to her high stature in the profession.

In addition to her impressive research accomplishments, Leakey has authored a number of professional scientific articles that should be of great help to those interested in her specialty. Likely because of her many contributions in her chosen area of inquiry, Leakey was named "explorer in residence" by the National Geographic Society. It seems likely that Leakey will continue to be fruitful in her research and other professional endeavors, thereby demonstrating her worthiness as a recipient of this distinguished award.

**MEAVE EPPS LEAKEY**

Meave Epps was born in London in 1942. She earned a Ph.D. in zoology from the University of North Wales in 1968 before accepting Richard Leakey's invitation to work on the paleontological site at Koobi Fora on the eastern shore of Lake Turkana in Kenya in 1969. In 1970, she married Leakey, the son of famed paleoanthropologists Louis and Mary Leakey. Since 1969, Meave Leakey's career has been spent working for the National Museums of Kenya.

In 1982, she was made head of the Division of Paleontology of the National Museums of Kenya. In 1989, she began working as coordinator of the National Museums' field research in the Turkana Basin. She resigned from that position in 2001.

Leakey's fieldwork in East Africa has been focused on fossil hunting that uncovers the origins of the earliest human ancestors. Her search for fossil remains in the Turkana Basin has been fruitful, with her fossil finds adding to the understanding of early hominids. The sites excavated are believed to be between 4 million and 8 million years old. Excavations near Lake Kanapoi in 1994 led to the discovery of early hominids.

In 1999, a research team led by Leakey discovered the fossilized skull and partial jawbone of an individual they named *Kenyanthropus platyops* ("flat-faced man of Kenya"). The fossilized skull was estimated to be 3.5 million years old. This find and others during the 1990s required reorganizing the evolutionary timeline for hominids.

Leakey is the author of numerous books and scientific articles on paleontology. Some of her most important writings include *Lothagam: The Dawn of Humanity in Eastern Africa* in 2000, *Stratigraphy and Paleontology of Pliocene and Pleistocene Localities West of Lake Turkana, Kenya* in 1988 (with John Harris), and *The Fossil Hominids and an Introduction to Their Context, 1968–1974* in 1978.

Leakey is the leading member of the Leakey dynasty of paleontologists. Her daughter, Louise, is actively following in her footsteps. Together, they are digging into the origins of humans in East Africa. In 2005, Meave and Louise were working with the Leakey Foundation and the National Geographic Society to fund the 5-year Koobi Fora Research Initiative in the Turkana Basin. The initiative expands the seasonal fieldwork to a year-round search and addresses questions about the origins and spread of humans from Africa to other parts of the world.

**LEAKEY, RICHARD E. F. (1944–)**

The paleontologist Richard Leakey was born and raised in Kenya, son of the famous paleontologist team, Louis and Mary Leakey. Influenced by his dynamic parents, the value of a traditional English education waned in the face of both adventures of new hominid discoveries and the diversity of life found in the African environment. After successful completion of his primary school education, Leakey attempted to further his education by attending the Duke of York. Contrary to previous success, his scholastic term at Duke of York was less than illustrious. Similar to his father's plight, the free, warm, and sympathetic association with the native populations of Africa led to social conflict for the young Leakey, eventually leading him to become a social outcast. However, the prospects of an African adventure allured Leakey from the halls of academia to the rugged African landscape that was a form of personal comfort. For Richard Leakey, who skipped classes and was fiercely independent, both his rebellious nature and the issue of dropping out of school were divisive

factors in the crippling of the relationship with his father. However, the decision that led to Richard's financial independence (due to his father's ultimatum and generosity) would eventually shape his future endeavors.

With monies secured by his parents, Leakey's wildlife venture earned him the respect and financial independence that he sought. This success continued and was furthered by the formation of his safari company shortly before Kenya's independence in 1963. During an excursion to Olduvia, he became aware of the geological formations at Tanganyika's Lake. The ensuing expedition yielded an exciting discovery, for evidence of a new fossil hominid was recovered. Although Richard was initially absent during its discovery, the recovery, interpretation, and announcement of this new species, *Homo habilis*, was left to the patriarch of the Leakey clan, his father Louis. The second expedition might not have had the same importance as the first expedition, but the fossils recovered were just as impressive.

Leakey married Margaret Cooper in 1966 (divorced in 1969) and later married Meave Epps in 1970. Between the two marriages, he had three children.

Leakey acquired additional professional responsibilities during this period. He served as director of the National Museums of Kenya (1968–1989) and director of the Kenya Wildlife Service (1989). His days in the field came to an end in 1993 when his plane crashed. Concerned with political corruption and environmental issues, Leakey's efforts for environmental protection and political reform had led to the creation of the political party Safina. Subjected to hostile intentions from political and criminal enterprises, Leakey continues to further his ideals through education and writings. His publications include *Origins* in 1977, *People of the Lake* in 1978, *The Making of Mankind* in 1981, and *The Origin of Humankind* in 1994.

Contributions and Perspectives

Similar to Charles Darwin (1809–1882) and Louis Leakey (1903–1972), Richard Leakey considered Africa as the evolutionary cradle of the human species. Although he was not a credited scholar, the influence of his parents and his naturalism led him to a historical approach within an anthropological framework. Within this historical approach, Leakey placed the evolution of the human species' history that can be traced back to the origin of bipedality in the African environment around 5 to 10 million years ago, although evidence of *Australopithecus afarensis* places the earliest known bipedal creature between 3 and 4 million years ago. From this point, both brain expansion (complexity is another issue) and stone tool use in Africa were seen between 2 and 3 million years ago. Major advancements in stone technology (for example, the Achulean) were seen between 1 and 2 million years ago, when the expansion of *Homo habilis* out of Africa coincided with an increase in meat consumption. With the first use of fire around 700,000 years ago, another major technological advancement (the Mousterian) led to the origins of modern humans in Africa around 200,000 years ago. However, the greatest advancements can be seen as stemming from the Agricultural Revolution around 10,000 years ago. From this point, divisions of labor and the creation of cities with larger populations made both the Industrial Revolution and the Technological Revolution possible. All this progress became possible through the refinement of hominid bipedality around 5 to 10 million years ago.

Although this post hoc analysis of human antiquity does possess an evaluative power, Leakey's analysis of hominid taxonomical structure becomes a point of interest. Unlike most taxonomical analysis that places the human species as sharing a common ancestor, *A. afarensis*, with other hominids, Leakey depicted our species as descending from an unknown hominid form. In this manner, a hominid taxonomical structure creates two parallel evolutionary branches: one consisting of the *Homo* line and the other for the *Australopithecines*. When placed in a hierarchy, an unknown species of *Homo* gave rise to *H. habilis*, and then *Homo erectus*, ending with the human species *Homo sapiens*. Parallel to the *Homo* line, *A. afarensis* gave rise to both *Australopithecus africanus* and *Australopithecus Boisei*, and *A. africanus* gave rise to *Australopithecus robustus*. Compared with the accepted phylogenetic analysis as performed by Randall Skelton and colleagues in 1986, *A. afarensis* gave rise to *A. africanus*, which then split into two branches: *H. habilis* and *A. robustus/boisei*. The interpretation of the evidence does become a point of inquiry. In the use of inference from molecular genetic evidence, as with Leakey's preference, it is important to implement extreme caution when classifying extinct hominid forms based solely on some unstandardized morphological characteristics.

Regardless of the interpretation of the evidence, Leakey's vitality and deep interest in our own humanity created an opportunity for open dialogue and research. Viewing the human species as a part of nature, it becomes clear that it is human's own responsibility to conserve their natural environment. With understanding and compassion, if not being subjected to utility, this process should be extended to all life, including the treatment of members of the human species. Perhaps stemming from his cultural environment, Leakey's political activity clearly depicts his concerns based on his earlier experiences. Although the plane crash ended his fieldwork, paleoanthropology will continue to benefit from the "Leakey luck" that has greatly enriched the field of anthropology. Work will continue by Richard's wife, Meave, and the couple's daughter, Louise. Richard Leakey, like his father Louis, will be remembered as one of the patriarchs of African paleoanthropology.

Legends are stories believed by the narrator to be true. Most stories, therefore, are based on actual experience or observations that have been cast into narrative form in accord with traditional models and established points of view. Legends need no datelines or the names of persons or places to authenticate them. They are over as events, but they live and survive in our memories due to their human interest. They are symbols of something of universal and perennial interest, ideal representations of human nature and the truth of life everywhere. Legends are the stories formed around the truth like crystal formed around a grain of sand. False addition or deductions from real facts may build them up by twisting the facts in the process of translating from primitive languages. As such, legends are unverified nonhistorical popular stories handed down by tradition from antiquity. Originally, they were limited to the lives of saints and gods or to collections of stories from particular religious and mythological backgrounds. There is a legend regarding the creation of the world in Middle America coming from ancient Aztec and Mayan people. Throughout the New World, there is a belief in multiple creations of which the present world is but one. In Middle American belief, there are normally four of these creations or, as

they are called, world ages. Movement through these ages is usually progressive, and the present age may acquire a special status as the fifth age, which is the sum of all other ages. The basis of this legend of five in four is expressed in the carving known as the Aztec Sun Stone, where the sign that names the present age movement is constituted by the signs that name the four previous ages: Water, Jaguar, Rain, and Wind. These signs are enclosed in the unending sign of the Twenty signs, running anticlockwise and enclosed by two year-snakes. The 16th-century Nahua manuscript known as the legend of the Suns tells us more about these world ages and their cataclysmic endings. During the first age (Water), humans were invented and molded from ash, and then everything was overtaken by water and people were transformed into fish. During the Jaguar age, the sun was eclipsed, and in darkness jaguars ate the people. Then came the Rain age, which ended in a rain of volcanic fire and ash. Then the Wind age, with its hurricane, came and men turned into apes. And the present age also is doomed

to earthquake and famine. The same sequence of cataclysmic events—flood, eclipse, eruption, and hurricane—occurs in other legends as well. According to Indian legends, the universe is said to have come into being out of chaos when Indra, the kind of the gods and the god of rains, or Vishnu, a solar deity, separated heaven from the earth. Then the sun rose, and from that spot, the naval of the earth, a great pillar was erected to prop apart heaven and the earth. This pillar is the axis of the world. There were now three worlds: Heaven, Earth, and the intervening Air or Ether. Although there are some obscure hints of an underworld as well, little is said about it in *Rigveda*, the basis of this legend.

The word *legend* is derived from medieval Latin *legenda* (“things for reading”) from the Latin *legendus* (“to collect, gather, or read”), meaning that the story or legend comes from some ancient book. As such, a legend is different from a myth or folklore because a myth in this particular context is a traditional story originating in a preliterate society

and dealing with supernatural beings, ancestors, or heroes who serve as primordial types in a primitive view of the world, and folklore is the traditional orally transmitted beliefs, practices, and tales of people. A legend is an ancient traditional story, or a cluster of stories, about a particular person or place. Besides godmen and saints, legends include elements of mythology, supernatural beings, or explanations of natural phenomena. They are often regarded as historical, although the elements of truth in legends cannot be examined, verified, and proved.

The legends denoting human relations with animals are also found in a number of ancient traditions, cultures, and literature. The heroes who

Source: Courtesy, Wikipedia.

are responsible for the good and bad in the lives of people appear as animals and men on different occasions. The ancient gods of Egypt, Greece, and India bear testimony to this. It hardly makes any difference whether *Coyote* of the American Indian tribes was a man or an animal to those who tell stories about him. Similarly, *Hanuman*, one of the most popular Hindu deities, is depicted as an ape, Ganesh is depicted with an elephant head, and the reincarnations of Lord Vishnu all are animal figures such as *Varah* (pig), *Kachchap* (tortoise), *Matsya* (fish), and *Narsinh* (half man, half lion). Moreover, the animals (e.g., *Kamdhenu*, the holy cow) help humans to achieve their ultimate goals. They are also the vehicles of gods such as *Laxmi* (owl), *Saraswati* (swan), *Ganesh* (mouse), *Vishnu* (hundred-headed snake), *Shiva* (ox), and *Yama* (buffalo). Similarly, the legendary relations are established between gods and nature. *Indra* is identified with rain, *Varun* with air, and *Agni* with fire. *Ganga*, *Yamuna*, *Godavari*, and *Narbada* are not only holy rivers but also goddesses.

Besides having the divine and semidivine element, the legends are associated with historical figures as well. On the one hand, there is a tendency to confuse legend with history and to accord them unduly. On the other hand, the postmodern school of history is laying a great emphasis on accepting legends as an important source material for history. As for their credibility and acceptance the antistructuralists argue that the line between belief and unbelief is very vague and thin and that it varies from culture to culture and even from person to person. Here even in the educated, learned, and sophisticated societies, legends of strange things from the past or present continue to be told and are usually believed. Moreover, one may argue that legends are not history but must accept that history often becomes legends. The real historical figures turn into legends sometimes during their own lifetimes or after death. It is very common with the tribal leaders; many of the tribal leaders who fought against injustice and raised rebellions have been deified and given the status of demigods, thereby acquiring legendary characters—*Birsa Munda* of Chhota Nagpur, “*Rani*” *Gaidinliu* of Nagaland, and *Gundadhur* of Bastar, to name a few. The most outstanding national heroes, such as the great Ashok, Shivaji, Maharani Laxmi Bai, Bhagat Singh, and Mahatma Gandhi in India, Alexander and Napoleon in Europe, and George Washington

and Abraham Lincoln in America, are legends of history. The social-cultural legends from living beings are scattered all over the world, be it Ludwig van Beethoven, Michelangelo, Leonardo da Vinci, Pandit Ravishankar, or Amitabh Bachchan.

The latest trend in legends is that of “urban legends” being used to denote something close to rumor and coming out of a mental state of anxiety that America is facing today after the terrorist attacks on the World Trade Center and Pentagon. The psychologist Chip Heath has explained that urban legends often evolve to include informational credentials that act as camouflage and make it harder for people to debunk them.

Extant lemurs inhabit the island of Madagascar along with other prosimians, the indriids and the aye-aye. Among the former are the “mouse” lemurs (cheirogaleids); the “sportive” lemurs (genus *Lepilemur*); the “gentle,” “wooly,” and “bamboo” lemurs (genus *Hapalemur*); varecias (genus *Varecia*); the ring-tailed lemur (genus *Lemur*); and various other lemurs such as black, brown, collared, macaco, and mongoose lemurs (genus *Eulemur*). As prosimians, all lemurs possess a grooming claw on the second pedal digit, and their six lower anterior teeth (with the central four being more slender than the lateral pair) form a variably elongate and procumbent toothcomb. *Lepilemur* is unique among primates in that it does not replace its upper deciduous incisors; the anterior region of the palate bears a keratinized cud pad. Mouse lemurs have somewhat elongate ankle or tarsal bones (primarily the calcaneus) and locomote by

leaping between more or less vertical branches. The other lemurs are hindlimb-dominated quadrupedals that are equally agile on the ground and in the trees.

Most lemurs are diurnal, but mouse lemurs and *Lepilemur* are nocturnal. Mouse lemurs are insectivorous and display a “noyen” type of social behavior

(i.e., females share a nest and territory that is overlapped by the territories of single males); they enter a state of metabolic slowdown or torpor while asleep. Male and female *Lepilemur* urine and feces mark the boundaries of their overlapping territories. *Lepilemur* is the only prosimian whose diet consists solely of mature leaves and that reingests its feces (caecotrophy) as a way of further processing its food intake. Other lemurs aggregate in variably sized groups of males and females and, depending on the species, are folivorous (leaf eating) and frugivorous (fruit eating) to varying degrees. *Lemur* and *Eulemur* scent mark territory with urine, feces, and glands (variably located on the wrists, neck, and/or forehead). *Lemur* is distinguished from *Eulemur* species in that it spends more time on the ground and its social behavior is based on a hierarchical arrangement of female dominance. The activity pattern of at least some *Eulemur* is cathemeral (i.e., sporadic throughout a 24-hour period), rather than diurnal or crepuscular, although under certain circumstances the same group of *Eulemur* may temporarily become nocturnal (and change their diet to nectar and pollen). *Hapalemur*'s ability to digest toxic bamboo shoots has allowed it to spread its range as bamboo replaces areas of primary forest that were lost to deforestation.

The systematics, phylogenetic relationships, and biogeographic history of extant lemurs are not without debate. Although a simple hypothesis is that primate diversity on Madagascar emerged after the chance invasion of a single ancestor (a historically favored scenario, most recently embraced by molecular anthropologists), comparative morphological studies suggest that mouse lemurs

may be more closely related to a loris–bushbaby group (for example, by virtue of a unique arterial pattern involving the carotid artery) than to any Malagasy group. In addition to alternative theories of indriid–adapid relationships, there is a case for multiple invasions of Madagascar. Among the nonmouse lemurs, *Lemur* has been united with

Hapalemur (due to the presence of wrist glands and the interpretations of some chromosomal studies), although detailed craniodental analyses indicate closer relationships between *Lemur* and *Eulemur* and between *Lepilemur* and *Hapalemur*.

LENIN, VLADIMIR I. U. (1870–1924)

Born in 1870, Vladimir Ilyich Ulyanov, who later changed his name to Vladimir Lenin, was the son of a civil service official in the Russian government. Lenin became interested in socialism and revolution when his brother Aleksander was executed in 1887 for

being part of a group that attempted to execute Alexander III. Shortly thereafter, Lenin studied law but was banished from the university for his revolutionary interests. He completed his studies independently, even though he became a professional revolutionary and not a lawyer. Because of his revolutionary activities, Lenin was exiled to Siberia from 1895 to 1900. During his exile, he wrote *The Development of Capitalism in Russia*. With this publication, Lenin showed that Russia depended on a capitalist-based economy. Within Russia at this time, the peasants were divided between a developing peasant bourgeoisie (capitalist farmers) and a peasant proletariat (farm laborers). The peasants between these two economic classes were disappearing. Russian industry was divided among traditional handicrafts, backward manufacturing, and a modern machine industry,

with a great deal of foreign capital invested only in the latter.

After returning from exile in Siberia, Ulyanov took the name Lenin and left Russia, joining with other Russian revolutionaries in Europe. In 1902, he wrote the pamphlet *What Is to Be Done*, maintaining that Social Democrats needed to be clear on the main principles of socialism: “Without revolutionary theory there can be no revolutionary movement.” In his pamphlet, Lenin wrote that unions, standing by themselves, would only lead to struggles over wages and working conditions; a socialist consciousness needed to be introduced from outside the working class. Lenin believed that, for the workers to learn to stand together, they must struggle against their employers, class society, and the state. This organization would need to be disciplined, conspiratorial, and centralized. The “party of a new type” would become the vanguard of the working class and would lead, but remain separate from, the broader democratic workers movement.

In 1904, Lenin completed *One Step Forward, Two Steps Back*. The intelligentsias were fixated on individualism and anarchism, and they had revulsion for discipline. The workers, because of their work lives, were familiar with discipline and self-sacrifice. Lenin wrote that intellectuals were too indecisive to be serious socialists.

Materialism and Empiriocriticism was written in 1908 to destroy the influences of *Machism* in the Socialist party. Ernst Mach argued that science cannot discover a reality independent of one's experience of that reality; that is, science records only one's experience of reality and not reality itself.

In *Materialism and Empiriocriticism*, Lenin stated that logic in science is the observation of the material universe, existing independent of the observer. Physical sensations are the direct connection to the external world. Every ideology is conditioned by its historical setting. Science is no different, yet science is valid independent of the observer to the degree that it corresponds externally to tangible nature.

Also in 1908, Lenin wrote *The Agrarian Program of Social Democracy in the First Revolution*. In this book, he clarified the peasant situation in Russia at the time. Most peasants in Russia were reduced farm workers or tenant farmers. Few peasants had enough land to

survive. A few were rapidly becoming like American capitalist farmers. The large feudal *latifundium* (large estates) remained. The latifundium were slowly developing into large farms modeled on the German Junker type. Lenin tried to prove that by breaking down feudalism, capitalism could develop. He explained that the demand for nationalization of the latifundium by the poor would not work at this early stage. The established market economy would simply make the state become the landowner, and rebellion would grow. Only by the expansion of capitalist relationships in the countryside would socialist consciousness grow among the poor peasants.

Lenin was in Switzerland when World War I broke out. He saw World War I as an imperialist war. He wrote in *Imperialism: The Highest Stage of Capitalism* that imperialism was “the final stage of capitalism” and that this war offered the prospect for a socialist revolution. Lenin recommended that the proletariat oppose the war and turn it into a civil war against the capitalist class.

Competitive capitalism of the early 19th century had become increasingly centralized (fewer competitive firms) and concentrated (larger firms). Monopoly capitalism was able to create larger surpluses by limiting competition. This meant that corporate capitalists were forced to export capital to ensure future profits. This became, for Lenin, a major distinction between the earlier competitive capitalism and its later descendant, monopoly capitalism. Competitive capitalism exported finished goods in exchange for raw materials produced in the poor areas of the world. Monopoly capitalism exported its capital to these areas. Capital was invested to create modern ways of extracting those same raw materials. Instead of the mines being owned by the local traditional elite, capitalists in the rich industrial nations owned them. This then increased overall capital on a world scale while arresting development in the main capitalist countries.

The principal feature of modern capitalism was the domination of monopolist consolidations by giant capitalist firms. The monopoly control was most firmly established when all sources of raw materials were controlled by a single joining of several large surviving firms. Monopoly capitalism, when a few highly centralized firms effectively dominated the economy, created imperialism out of its own needs. To find continued profits in an already overly developed economy at home, investments flowed to less developed areas of the world where the capitalist

economy had not reached a saturation point, thereby making profits much higher. Export of capital was the fundamental principle of imperialism. The export of capital greatly influenced and hastened the growth of capitalism in those countries to which it was exported.

In *The National Question*, Lenin recognized the right of national self-determination, although he was aware of the problem of national chauvinism. He believed that internationalism was central to any hope for socialism.

With the revolution of March 1917, the German government allowed Lenin to return to Russia, insisting that he go in a sealed railway car so that the followers of his revolutionary ideas would not know of his passing.

Lenin stated in his *April Thesis* that Russia was now ripe for a socialist revolution, arguing that the provisional government represented the bourgeoisie, whereas the Soviets represented a revolutionary democratic dictatorship of the proletariat and peasantry, with the proletariat leading the poor peasantry toward the full power of the Soviets of Workers' Deputies. In *State and Revolution*, Lenin claimed the workers could not simply take control of the existing state; they needed to smash it. He proposed that the new workers' state replace the police and military with armed workers' militias. Elected representatives accountable to the workers' councils and subject to popular recall would replace the bureaucracy. All officers would be paid workers' wages. In Lenin's proposal, when the return of bourgeoisie was overthrown, the state would wither away.

In November 1917, the Bolsheviks, led by Lenin (who had returned to Petrograd), overthrew Aleksander Kerensky's regime and established a Soviet government. Lenin became chairman of the Council of People's Commissars. A bitter civil war followed, and the Bolsheviks won. But because Western Europe failed to have a successful socialist revolution of its own, and because Russia was in economic ruin, Lenin was forced to delay establishing a socialist government immediately; instead, market reforms were put into place. In *Left Wing Communism: An Infantile Disorder*, Lenin criticized leftist elements in the West for neglecting parliamentary tactics and legal opportunities to create their own socialist revolution. He reiterated the importance of all communist parties to become centralized and disciplined and to follow the lead of the Russian party. Lenin died

January 21, 1924. He did not live long enough to see a successful conclusion to his life's work or socialism in Russia. He is remembered most due to a legacy created by his followers in the new Soviet Union. In death, he became more important to the evolution of Marxist theory than he ever had been in life. For the remainder of the 20th century, the phrase *Marxism–Leninism* became the definition of orthodox Marxism.

LEONARDO DA VINCI (1452–1519)

Leonardo da Vinci represented the transitional stage between the early period of the Renaissance, with its humanist links to Classical antiquity, and the later Renaissance, with its scientific and technological achievements that foreshadowed the modern Western world. In fact, he was one of the dominant artistic figures of this age. During his later years, da Vinci's great ambition was to discover the natural laws underlying the processes of nature and the flux of reality. He became more and more interested in

science, especially scientific illustration. The thoughts and creativities of his all-encompassing mind still remain an inspiration to the human species.

The Italian Renaissance (1401–1600) represented not only the rebirth of humankind out of the unenlightened years of medieval beliefs and superstitions but also a return to reason and empiricism; all aspects of society and culture were changing. It presented views of the human species and the universe that challenged the old, entrenched, and dogmatic Aristotelian, Ptolemaic, and Medieval conceptions of things. In fact, a new anthropology and the modern cosmology were emerging.

Wandering through the Alps and the mountains of Tuscany, da Vinci was fascinated by the beauty and detail of the geological and paleontological evidence about him and its far-reaching implications. His own magnificent landscapes attest to his love for physical nature, as is clearly seen in his painting *The Virgin of the Rocks*. To da Vinci, the rock strata with their fossils suggested a story considerably different from the interpretations given by most thinkers in antiquity. (Although he was the father of biology and made contributions to taxonomy and embryology, Aristotle himself had held to the eternal fixity of all terrestrial plant and animal forms—including that of the human species—within the hierarchical great chain of being. It was a safe and secure worldview.)

Because numerous marine fossils of various sizes and shapes were found in many different layers above the sea level, da Vinci knew that natural history had not been eternally fixed in space and time. Searching for a scientific and rational explanation, he rejected all religious interpretations of creation and destruction. To account for the marine objects at the tops of hills and mountains far removed from the sea, his mind leaped ahead of contemporary thought to embrace conceptions of both geological catastrophism and historical uniformitarianism (ideas that are hard for some thinkers to accept even today), and it may have even anticipated the scientific theory of biological evolution.

Da Vinci studied the fossil evidence in these layers of mountain stone: various crabs, sea snails, oysters, corals, scallops, cockles, marine shells, and cuttlefish as well as traces of worms and the bones and teeth of fishes. To explain rationally the geopaleontological nature of things, he took time and change seriously. Holding to the plasticity of the earth, da Vinci held that there had been periodic upheavals of mud layers

from the ancient bottoms of the salt waters. Such mud layers formed hills and mountains, and erosion by rivers later uncovered the strata of marine fossils. In short, the bottoms of seas had become the mountain ridges of modern time.

Like Xenophanes, da Vinci recognized the biological and historical significance of the fossil shells and marine animals he found embedded in mountain rocks at high elevations. He rightly held them to be the remains of creatures that had once lived in the seas or on the beaches of the past and had been lifted up later. Da Vinci also ascribed to the earth an antiquity of more than 200,000 years. This was an incredible insight on his part given that most thinkers at the time held fast to the biblical account of a Creation that had taken place around 6,000 years ago or did not take history and change seriously. Da Vinci pushed back the horizon of time. He also recognized the similarities among humans, apes, and monkeys. He even speculated on the process of erosion, sedimentation, and fossilization or mineralization.

Reminding one of Plato, da Vinci had once written, “Let no one who is not a mathematician read my works.” Yet during his later years, he changed his view of the universe from a mathematico-mechanistic model to an organismic interpretation of the cosmos. All nature is now vitalized in da Vinci’s cosmology. As such, he viewed the earth itself as a living organism. He wrote that animals (including the human species) are the image of the world; a human is a microcosm, whereas the universe is the macrocosm, with the two being identical in their nature. Like Heraclitus, da Vinci held that everything in the world is in a state of flux; the basis of all phenomena is not mathematics but rather life, movement, and change.

In his cosmic vision, da Vinci rejected the earth-centered model of the universe. Although he held to a fixed but spherical earth and the fixed ceiling of stars, he did anticipate both the telescope and the universality of gravitation. Da Vinci’s cosmology supported a plurality of worlds and both the eternality and infinity of the universe. He shed theology for a monistic and naturalistic philosophy supporting pervasive necessity and simplicity, continuous change, and areligious pantheism (recall the similar thoughts of Giordano Bruno).

Da Vinci saw time as the evil destroyer of all things. He was fascinated and obsessed with catastrophic destruction involving wind, water, and fire (his

sketches depict the destructive forces of the natural elements). Like the later Neptunists in geology, da Vinci held water to be the basic geological modifier of the surface of the earth. He even envisioned the natural end of the world as a result of the disappearance of all water into the interior of the earth, followed by fire destroying all terrestrial life, including the human species. This vision was a far cry from the Aristotelian view of an eternally fixed, safe, and secure world.

In 1516, after years of aimlessness and restlessness, da Vinci was invited by the French king to spend the remainder of his life in France. In May 1519, he died at Cloux and was buried in the cloister of the Collegiate Church of St. Florentin in Amboise. He had lived at the threshold of the modern world. He himself shook the foundations of art and science and envisioned the shape of things to come. Recognizing the ultimate unity of nature, his worldview foreshadowed the modern image of humankind within the universe and anticipated our scientific and technological world.

LEVALLOISIAN TRADITION

The Levalloisian tradition is a Lower and Middle Paleolithic method of stone tool production whereby stone flakes are removed from a carefully prepared stone core in such a way as to predict the size and shape of the flakes removed and to maximize the number of flakes produced per core. The evolution of the Levalloisian tradition is significant not only because it marks an important technological change from simple core tools to more complex flake tools but also because it reflects changes in hominid cognition in that the complexity of a stone tool tradition

is taken by archaeologists to be an index of cognitive complexity.

The Levalloisian tradition gets its name from a quarry in the northern Paris suburb of Levallois-Perret. As an archaeological concept, it is less than 100 years old, and for much of that time it was viewed as a monolithic typological construct where the final products of the flaking process were of paramount concern. Although what exactly constitutes a final Levalloisian product is debated, it is generally agreed that there are three basic final products: flakes, blades, and points. Flakes vary in shape but are generally oval or rectangular in outline, blades are long and narrow and usually twice as long as they are wide, and points are triangular. Levalloisian stone cores are sometimes referred to as “tortoise-shaped” cores due to their distinctive dome-like appearance.

In contrast to earlier ideas, recent research has documented a wide range of morphological variability among Levalloisian cores and flakes in time and especially space. This tradition has now been identified in Europe, Africa, Asia, India, Australia, and most recently Japan. Archaeologists became concerned with Levallois variability after an analysis of classic Levalloisian end products from Levels 1 and 2 of the Boker Tachtit site in the Negev desert of Israel were discovered to have been produced from an atypical Levalloisian flaking and core preparation sequence. This realization led archaeologists to understand the Levalloisian tradition as a dynamic process that varied regionally, temporally, and perhaps culturally.

The Levalloisian tradition was first thought to have originated as a single invention at a single place in a single time and to have eventually spread throughout the Old World by diffusion. The continental geography of its invention is an issue of debate. Some monocentrists argue for European origins, where the evolution of the Levalloisian tradition is seen as an accidental development, whereas others look to Africa for its origins. Proponents of the African hypothesis argue that the Levalloisian tradition is a distinctly African phenomenon that spread to Europe and other parts of the Old World some 250,000 years before the present as anatomically modern humans migrated out of Africa. Still, the widespread geographic variability observed in Levalloisian assemblages throughout the Old World provides strong evidence for polycentric origins and suggests independent invention in multiple places and times. The ultimate cause of such widespread regional variability is currently unknown,

but archaeologists hypothesize that it may be the result of the combined effects of migration events, diffusion, stone raw material variability, and variations in use.

The archaeological concept of the Levalloisian tradition has been in a near constant state of transformation since its recognition nearly 100 years ago. Consequently, archaeologists are simply not sure how to interpret its temporal, spatial, and formal variability, let alone its origins. To combat this, archaeologists have outlined the major problems facing Levalloisian scholars in an effort to direct future research toward the resolution of these issues. The first problem questions the Levalloisian tradition itself as a unified analytical concept. That is, is Levalloisian technology only one of many technological solutions within a single flaking strategy, or is Levallois the only possible outcome? The second problem concerns the definition of intended Levalloisian end products in the sense that archaeologists must decide what constitutes an end product as well as the role of predetermination in its production. The third problem challenges archaeologists to deal with variability in the Levalloisian tradition, especially in terms of the role that individual cognition and standardization play in the flaking sequence. Finally, archaeologists must also deal with Levalloisian terminology; for example, is the Levalloisian tradition only a method of core preparation, or does it also refer to the specific organization of flake scars and ridges on the surface of the core? These questions, among others, will continue to drive the archaeological understanding of the Levalloisian tradition for the next 100 years.

LEVINAS, EMMANUEL (1906–1995)

Emmanuel Levinas was a major figure in postwar French philosophy, although he was born in Lithuania. Significantly, he was Jewish in origin; this was always important in his philosophy, which sometimes referred to his Jewish (although he seems to have been agnostic about the existence of God) and Zionist convictions. He studied with Martin Heidegger in Germany, and his work exhibits deep ambiguity about Heidegger, presumably at least partly due to Heidegger's support for the Nazis in 1933. There could be no Levinasian philosophy without Heidegger, but Heidegger is often the target of Levinas's philosophy, as are G. W. F. Hegel and Edmund Husserl. Levinas's emergence as a French philosopher belongs to the time when the "three H's" were at the center of academic philosophy. He suggested that they belonged to a Greek philosophical tradition in which ontology (the study of being and types of beings) is taken as the first philosophy. The Jewish tradition took ethics as the first philosophy, according to Levinas, and therefore offered a correction to the Greek tradition. Levinas did not, however, refer to Jewish philosophers; he meant that the Torah and the tradition of its interpretation assumed a position in which ethics was the first philosophy. Levinas himself taught Talmud classes for children. Nevertheless, his philosophy can

be understood only against the background of the European tradition since the Ancient Greeks. His work began with research on the phenomenology of Edmund Husserl and emerged in mature form decades later in *Totality and Infinity* (first published in 1961). In that book, he suggested that the ontological tradition of Greek philosophy was a philosophy of power, of the state, of the supremacy of the I, and of war. He opposed that with the Jewish ethical tradition in which the Other is supreme and the I, or the Same, can exist only in its responsibility to the Other. The Other appears phenomenologically in the face, with which the I cannot avoid an ethical relation. Even if the I murders the Other, the Other is still supreme for the I. The I cannot exist without recognizing the Other, without recognizing that the sameness of the self depends on alterity. The self can have a relation with the world, which is its only way of existing meaningfully, only if it recognizes that its own self belongs to what is outside the self. Levinas partly explained that in relation to notions of the Gift, of the relation of giving with no return, with clear echoes of the work of Marcel Mauss. Despite his reservations about the European philosophical tradition, Levinas defined his position through Plato, Descartes, and phenomenology. From Plato, he took the idea of the form of Good as the sovereign form before the form of Being. From Descartes, he took the idea that God (as a form of otherness) is an unavoidable assumption for me and exists in excess over, or transcendence of, my being. From phenomenology, he took the goal of describing the contents of consciousness, and their necessary structures, in a manner that pays particular attention to habitation, the body, the erotic, and language. His later work, particularly *Otherwise Than Being* (first published in 1974), also has traces of a critical dialogue with his friend Jacques Derrida in which he responded to Derrida's claims that his position was an act of metaphysical violence against the "ontological" tradition that replaced ontological metaphysics with his own metaphysics, in which abstract truth is said. Levinas's response was to emphasize the distinction between the act of saying as an ethical operation open to the other and the contents of what was said as more enclosed, along with a general attempt to write out any elements of the ontological tradition that might have appeared in his own work.

LÉVY-BRUHL, LUCIEN (1857–1939)

The anthropologist, philosopher, and sociologist Lucien Lévy-Bruhl is known for his controversial understanding of the minds of indigenous people. His highly influential writings led to a new method of analyzing illogical thought patterns as well as new ideas regarding primitive religion and mythology.

Lévy-Bruhl's early work focused on French, German, Jacobean, and Comtean philosophy, whereas his later work shifted toward the mental functions and emotions of indigenous people. Lévy-Bruhl's theories were based on his own research as well as on accounts gathered by other ethnographers, missionaries, and travelers. He was concerned with what he called the study of "primitive mentality." This work was Lévy-Bruhl's reaction to Émile Durkheim's ideas, which were extremely popular in France at the time.

In Lévy-Bruhl's *Les Fonctions Mentale dans les Sociétés Inférieures* (How Natives Think), published in 1910, he stated that indigenous people's thought processes were different from those of modern humans. He believed that their way of thinking lacked logic because they were unable to think abstractly. Instead, Lévy-Bruhl argued, indigenous people's minds focused on the supernatural. Therefore, he believed that indigenous methods of thinking reflected their beliefs in magic instead of focusing on the reality of human relationships and experiences. Lévy-Bruhl continued to develop these theories in *La Mentalité Primitive* (Primitive Mentality), published in 1923, and *L'Âme Primitive* (The "Soul" of the Primitive), published in 1928. His later work, *Carnets* (Notebooks), published posthumously in 1949, suggested a shift away from his earlier statements that primitive people were illogical. In this book, Lévy-Bruhl wrote about two different thought processes: one based on the natural and the other based on the supernatural.

In 1978, Lévy-Bruhl earned his degree in philosophy from the Ecole Normale Supérieure. Before enrolling at the University of Paris to work on his Ph.D., Lévy-Bruhl taught philosophy at the University of Poitiers and the University of Amiens. He finished his doctorate in 1884 but continued teaching until he was hired as titular professor of the history of modern philosophy at the Sorbonne in 1899. In 1904, Lévy-Bruhl became the chair of the history of modern philosophy department. He also served as editor of the *Revue Philosophique de la France et de l'Étranger* (Philosophical Review of France and Abroad). He continued to work at the Sorbonne until 1927. In 1925, Lévy-Bruhl assisted Marcel Mauss and Paul Rivet in the founding of the Institute d'Etnologie at the University of Paris.

LIBBY, WILLARD (1908–1980)

Willard Frank Libby was an American chemist whose technique of carbon-14 (or radiocarbon) dating provided an extremely valuable tool for archaeologists, anthropologists, and earth scientists. For this development, he was honored with the Nobel Prize in Chemistry in 1960. Libby was born in Grand Valley, Colorado, on December 17, 1908, to Ora Edward Libby and his wife Eva May. He attended grammar and high schools near Sebastopol, California, between 1913 and 1926, moving to the University of California, Berkeley, in 1927. He received his B.S. in 1931 and his Ph.D. in 1933. After receiving his Ph.D., Libby spent the 1930s building sensitive Geiger counters to measure weak natural and artificial radioactivity. He worked for 2 years as the personal research assistant to G. N. Lewis on the Berkeley campus. In 1939, he became an instructor in the College of Chemistry

at Berkeley, and he later became an assistant professor. In 1941, Libby was awarded a Guggenheim fellowship, for which he spent most of that year at Princeton University. With the start of U.S. involvement in World War II, he moved to New York and joined Columbia University's Division of War Research to work on the Manhattan Project with Harold Urey (Nobel Prize in Chemistry, 1934) alongside Glenn Seaborg (Nobel Prize in Chemistry, 1951). Libby was responsible for the gaseous diffusion separation and enrichment of uranium-235, which was used in the atomic bomb that was dropped on Hiroshima, Japan. Most separation was accomplished by gaseous diffusion of uranium hexafluoride (UF₆), but other techniques were employed as well. The bulk of this separation work was done at Oak Ridge, Tennessee. Libby also showed that tritium is a product of cosmic radiation. In 1945, he became a professor at the University of Chicago in the Department of Chemistry and Institute for Nuclear Studies (now the Enrico Fermi Institute for Nuclear Studies). It was during this chapter in his life that he earned the international renown for which he is regarded today.

Libby had available to him two invaluable facts when he conceived of the carbon-14 dating method. First, he was intimately familiar with the 1932 discovery of the neutron by Sir James Chadwick (Nobel Prize in Physics, 1935), who was involved in the Manhattan Project. Second, he was familiar with the work of Martin Kamen and Samuel Ruben, who in 1940 used the cyclotron of E. O. Lawrence (Nobel Prize in Physics, 1939) at Berkeley to bombard graphite and discover radioactive carbon-14 (an isotope of carbon) and found that it had a half-life of approximately 5,700 years. In addition, other researchers during the 1940s had found that some of the nitrogen in the atmosphere was turned into carbon-14 when hit with cosmic rays. In 1947, Libby, who was then at the Institute for Nuclear Studies, figured that a plant would absorb some of this trace carbon-14 while it absorbed ordinary carbon dioxide in photosynthesis. Once the plant died, it could no longer absorb carbon, and the carbon-14 it contained would decay with a known half-life without being replaced. Therefore, if the concentration of carbon-14 with respect to the stable carbon-12 left in the remains of the plant could be calculated, the amount of time that had passed since the plant had died could be determined because the unstable radioactive carbon-14 isotope decays at a measurable rate on the

death of an organism. With postdoctorate James Arnold, graduate student Ernie Anderson, and a \$5,000 grant, Libby led a team that developed carbon-14 dating using a highly sensitive Geiger counter, a logical development from his 1930s research. He tested his process on objects of known age, such as timbers from Egyptian tombs. The tests proved to be reliable, and it was assumed that this technique was accurate for organic objects that were tens of thousands of years old. For his work on carbon-14 dating, Libby received the Nobel Prize in Chemistry in 1960, joining fellow Alpha Chi Sigma fraternity members Seaborg and Linus Pauling (Nobel Prize in Chemistry, 1954). In 1954, while at Chicago, Libby became the first chemist ever appointed to the Atomic Energy Commission. In that capacity, he headed President Eisenhower's international "Atoms for Peace" project and studied the effects of radioactive fallout. In 1959, he became a professor of chemistry at the University of California, Berkeley, a position he held until his retirement in 1976. He taught honors freshman chemistry from 1959 to 1963 (it was a university tradition that senior faculty teach this class). He was also director of the University of California statewide Institute of Geophysics and Planetary Physics (IGPP), which was an exciting post during the time of lunar landings. He served in that capacity until his death. He also started the first environmental engineering program at the University of California, Los Angeles, in 1972. Throughout his long career, Libby wrote many articles and books, including *Radiocarbon Dating* (1955), which went through several editions. He was the recipient of several other awards, including the 1959 Albert Einstein award. Even brilliant men such as Libby could sometimes get things wrong. For example, Libby once suggested that the Tunguska event might have resulted from a small piece of anti-matter from space. The actual cause is now thought to have been a comet. He died in 1980 in Los Angeles.

LIFE CYCLE, HUMAN

Theorists who have written about the human life cycle include Sigmund Freud, Jean Piaget, Lawrence Kohlberg, Erik Erickson, and Daniel Levinson. They usually describe universal stages that people pass through during their lives and present the life cycle as one where people progress toward certain goals. Some theories, such as Freud's, were based mainly on speculation about what "must" occur in individuals in terms of oral, anal, and phallic stages of infancy and the later latency and genital stages. The oral stage (birth to 1 year) focuses on the conflict that the infant experiences between pleasure and pain from the mouth, the pleasure of food, and the pain of its denial. The anal stage (1–3 years) looks at the anus as a source of sexual pleasure and control, and the phallic stage (3–6 years) focuses on the genitals and a love/hate relationship with the parents. The latency stage (6 years to puberty) involves redirecting sexual energy to activities of the larger society. The genital stage (puberty to adulthood) involves becoming a mature adult in a heterosexual relationship. Others theories, such as Piaget's, were based on research on children. For example, Piaget did research on how children developed different ways of thinking. Today, the most influential of these theories is that of Erickson, who developed an eight-stage model of human development that modified Freud's theory to work better with non-Western cultures. Erickson looked at non-Western cultures, for example, how the Sioux, who freely breast-fed children up to 3 years of age and had a relaxed method of toilet training, produced generous adults, whereas the Yurok, who breast-fed children for 6 months and had strict rules

against urinating in the Klamath River, produced suspicious and miserly adults.

Although all of these theories have influenced particular anthropologists, many anthropologists have ignored them because they say such theories represent at best the Western life cycle and not the life cycles of even all members of Western society. Anthropologists who look at the life cycle are more likely to describe the four basic stages of the life cycle as birth, puberty, marriage, and death and to describe how people in different parts of the world think about these and the practices associated with them. The work of Arnold Van Gennep (1873–1957) has had a lot of influence in how anthropologists deal with the life course. In *The Rites of Passage*, Van Gennep described specific rituals that mark transitions in a person's social life in various societies in terms of the life cycle rituals related to pregnancy and childbirth, birth and childhood, initiation rites, betrothal and marriage, and funerals. These rituals move people from one social position to another. People often mark these changes in age-based identities with bodily mutilations such as scarification and circumcision.

Other anthropologists have looked at age grade and age sets, where males or females move into groups of approximately the same age, sometimes according to rites of passage and sometimes not. People in each age grade or age set take on specific roles. Thus, among the Tiriki of Kenya as described by Walter Sangree, adolescent boys undergo an initiation into an age grade at puberty. The Tiriki have seven named age groups, with each involving males who were initiated during the same 15-year period. Although it has changed over the years, it had the following form in 1939. Small boys entered the first age group, which consisted of boys up to 10 years of age. The next group consisted of 11- to 25-year-olds who in the past were divided into those who were initiated or uninitiated. The third consisted of men ages 26 to 40 years and was made up of warriors. The fourth group consisted of men ages 41 to 55 years and was made up of older warriors. The fifth group consisted of men ages 56 to 70 years and was made up of judicial elders. The sixth group consisted of men ages 71 to 90 years and was made up of ritual elders. The last group consisted of men ages 91 to 105 years and was made up of deceased or senile elders. Many anthropologists have written about age sets and age groups as ways for people to find help outside of groups based on kinship or marriage.

Many anthropologists in the United States dealt with the life cycle in terms of the culture and personality approach. Ruth Benedict wrote that the Japanese learn from the early years to subordinate individual desires to the needs of the group, with an emphasis on shame. Margaret Mead's studies showed that child raising greatly influences gender roles in a society, and subsequent studies have confirmed this despite controversy about Mead's methodology and interpretation of data. Geoffrey Goffey developed the "swaddling hypothesis" that linked swaddling to the intense mood swings of Russians in that swaddling immobilized infants for periods of time and then freed them to have intense social interaction.

John Whiting began another approach to the life cycle when he wrote an early ethnography about a life cycle of Melanesian people titled *Becoming a Kwoma* in 1941. It described how their culture affected the Kwoma from childhood to adulthood. He and the psychologist Irving Child then used the Human Relations Area File (HRAF), which had data on hundreds of societies, to write *Child Training and Personality* in 1953. In this book, they looked at differences in child-training customs in different cultures using elements of Freudian and behavioral psychology. The most impressive statistical correlation they discovered in their data was that the age of weaning and the severity of weaning had a strong correlation with people's oral explanations of illness. However, the HRAF data often involve a judgment call, so much of Whiting and Child's statistical data are suspect. Whiting also introduced the idea that societies where boys had a strong identification with their mothers have severe initiation rites that represented symbolic castration. However, many doubt this as well because some evidence shows that boys who grow up without a strong male figure actually act in exaggerated male ways. Later, Beatrice Whiting (John's wife) and Child developed the contrast between dependence training and independence training. This theory states that some societies focus on training children in such a way that promotes group solidarity and working together, whereas other societies emphasize individualism and self-reliance. Positive stimulus to promote dependence training includes nursing children for an extended period of time, whereas negative stimulus includes punishing aggressive behavior toward others. Positive stimulus to promote independence includes giving children their own private space at an early age and showing

toleration of aggression and competition, whereas negative stimulus includes nursing children for a shorter period of time and giving less attention to young children. Whiting and Child said that dependence training produces children who work well in groups, whereas independence training produces children who focus on individual success.

A recent approach to the life cycle draws on ideas from the French sociologist Marcel Mauss (1872–1950). One of those to develop Mauss's ideas, Paul Bourdieu, looks at life in terms of different types of capital—economic, social, and cultural. He says that these different types of capital create different opportunities for people not only in different societies but also within the same society. Those who follow this approach say that mental life is not universal but rather is influenced by cultural traditions and practices involving issues such as gender and kinship organization. Those drawing on Mauss's writings on bodily techniques talk about how the body is a part of both nature and culture, so that culture determines how people do basic things such as sitting. They write about how birth is biological but changes people's social roles and relationships, so that bodily events are inseparable from social ones. One's bodily experiences within a particular culture determine one's possible life course; one's life cycle depends on one's unique lived situation. Similarly, the life events approach says that people's lives depend more on the events of their lives than on their age, whereas the life span approach emphasizes individual differences and how change can take place in many ways.

LIFE, CHARACTERISTICS OF

The concept of life belongs to the basic cognitive endowment of every human. This deep anchoring makes it difficult to define life. Everyone has an intuitive understanding of how a living object should look and how it should behave, but for scientific purposes it is necessary to make this implicit and vague knowledge explicit and clear. How else should we identify extraterrestrial life on other planets—or artificial life in the computer?

A classical strategy of defining life, which can be traced back to Aristotle, involves listing characteristics of living beings. A modern biologist would enumerate at least three essential properties: metabolism, self-reproduction, and mutability.

- *Organisms metabolize.* There is a permanent exchange of matter and energy going on between organisms and their physical environment to build and preserve their physical structure.
- *Organisms reproduce themselves.* Organisms transmit at least a part of their genetic information to their offspring. This information is necessary for the structural and functional development of an organism.
- *Organisms are mutable.* Their self-reproduction is not completely perfect, so it is probable that even offspring of asexually reproducing organisms show genetic variation if compared with their parents.

Like any list of characteristics of life, our proposal has two fundamental defects. First, there is at least one important borderline case that turns out to be very difficult to classify. Viruses have no metabolism of their own, so they need a host cell to be supplied with energy for their self-replication. Do they alternate between life and death—alive whenever they have invaded a host cell and dead whenever they are outside a host cell? Second, there is a class of nonliving

objects that possess all of the characteristics on our list. Crystals grow in saturated solutions by replicating their highly symmetrical spatial structure. This process is not perfectly exact, so variations can occur in the crystal structure. In addition, one can detect a bidirectional metabolism; the building blocks of crystal growth are molecules coming from the solution, and the growing crystal radiates heat into the solution.

Both examples indicate that our list of characteristics of life contains only necessary, but not sufficient, properties for the identification of living systems. This is no surprise if we adopt an evolutionary perspective, which explains organic life as a result of natural history on Earth.

Because evolutionary theory will also address the problem of the origin of life, it must construct models for the prebiotic chemical evolution of the first self-reproducing macromolecules. By so doing, evolutionary theory presupposes that there is not an ontological cut between living and nonliving natural objects; rather, there is a physicochemical continuum. Consequentially, the evolutionary biologist cannot draw a sharp conceptual distinction between living and nonliving systems. But a complete list of necessary and sufficient characteristics of life would assume the possibility of both a clear ontological cut and a conceptual cut between prebiotic and biotic natural objects.

Darwinian evolutionary theory proposes that organisms are objects that are shaped by natural selection. A way out of the difficulty of defining life, then, is to characterize it by the natural dynamics of its origin and evolution. To do so, we must state the laws structuring this dynamics and the boundary conditions under which these laws act.

Natural selection is a dynamic process in systems in which struggle for survival occurs. That happens whenever a population of varying elements (for example, macromolecules, organisms) self-reproduce under restrictions on growth (on primitive Earth, in the ecological environments of today). We thereby take up the characteristics of life listed earlier but now integrate them into an evolutionary perspective.

How complex the resulting elements of the systems should be to call them “living,” then, is clearly a normative decision that cuts into a continuous natural history according to our respective research interests. So a list of characteristics of life is meaningful but in a specific research context. If we are, for example, interested in the origin of genetic information, the takeoff

of life will be the appearance of self-replicating macromolecules.

A famous example of how to follow this strategy of embedding characteristics of life into an evolutionary perspective is Jacques Monod’s *Chance and Necessity* (1970). This French molecular biologist defined two principal properties of living systems that he called “invariance” and “teleonomy” (from ancient Greek *telos* aim, and *nomos* law). Whereas invariance is the ability of a system to reproduce its structure correctly, teleonomy is the property of a system that is structured so as to realize a project by its behavior. Monod saw no dualism between invariance and teleonomy because the behavioral teleonomy of an organism involves, in the last analysis, transmitting the genetic information that is needed to reproduce its structure. Monod explained this functional dependence of teleonomy on invariance by assuming the temporal precedence of invariance over teleonomy both in the general evolution of life and in the specific development of individual organisms.

Modern biology has investigated both the material and functional aspects of this priority of invariance to teleonomy. The concept of biological information captures the functional dimension of this priority because it designates all processes in living systems in which a biochemical structure instructs the construction of another biochemical structure by means of a code. Taking the example of the gene, its functionality as hereditary information relies not only on its material stability in evolutionary processes but also, and above all, on the existence of a genetic code that relates the biochemical structure of a gene to the biochemical structure of a protein. Thus, the material structure of a gene is biologically relevant only insofar as it is, by its hereditary function, an information carrier between an organism and its offspring and, therefore, subjected to natural selection.

The concept of information is used here not in a metaphorical manner that would, if taken literally, impute an intention or even a consciousness to all living systems. Instead, information must be understood in a naturalistic way as a concept that can describe the functional architecture of the physicochemical structures that build up a living system. If Monod was right in giving self-reproduction priority over any other property of organisms, the concept of information is basic to every list of characteristics of life.

**ARTIFICIAL LIFE**

Within the discipline of anthropology, a number of scholars have begun to examine the ever-expanding subfield of synthetic anthropology, which examines artificial beings, worlds, and languages as a means of reaching a more comprehensive understanding of human beings. Recent advances in robotics seem to have brought science fiction to life, intriguing the general population as well as anthropologists and other scholars. In February 2005, the U.S. government announced that it had accelerated its development and use of what has popularly become known as "robot soldiers." Far more than being entertaining, the use of artificial soldiers is predicted to have enormous impact on saving the lives of American soldiers engaged in reconnaissance missions as well as in actual combat. The army predicts that robot soldiers will be ready for the battlefield in less than a decade. Financing the robot soldiers will raise the cost of the Future Combat Systems (FCS) project to \$127 billion, making it the most expensive military project on record.

The United States is already using unmanned aerial vehicles (UAVs), such as the Shadow, the Raven, and the Ignat, to expand military capabilities in Iraq. The military also plans to employ an Extended Range Multi-Purpose (ERMP) program that will expand the capabilities of UAV systems, which are projected to number 8,000 by 2010. These systems may be used for border patrol and homeland security as well as in combat situations.

Army robots are the result of ever-advancing technologies that have allowed the military to plan

for a time when each human soldier will be able to tap into the resources of robotic trucks and planes with up-to-date knowledge of targets, reconnaissance, and communication. As a result, soldiers will be able to supplement human instinct with scientific knowledge when making tactical decisions. As the technology behind the robot soldiers advances, so will their abilities and uses. By the middle of the 21st century, robots are expected to become autonomous, rather than being controlled by soldiers using laptop computers. While some future robots will look like humans, others may be disguised as hummingbirds, tractors, tanks, cockroaches, or even dust.

Military visionaries began planning military uses for robots as early as the 1970s, and the new robot soldiers were preceded by less advanced models. In the spring of 2003, the army employed "Matilda" (Mesa Associates' Tactical Integrated Light-Force Deployment Assembly) in Afghanistan. About the size of a dog, Matilda has a retractable arm and claw. This robot was ideal for traversing mountainous regions, seeking out members of terrorists who might be using the mountains for cover. Equipped with a video camera and sensors designed to identify the presence of toxic gases or other potentially dangerous substances in the air, Matilda was also used in Afghanistan to test for the presence of possible booby traps and to precede soldiers into tunnels or other tight spots. Robots have been used in Iraq since the beginning of the war to detect mines and to serve as armed sentries at weapons depots. A robot capable of firing 1,000 rounds a minute was expected to be deployed on the frontline in Iraq in the spring of 2005.

**UNITY OF LIFE**

The comparison between human genetic instructions (genomes) and those of other species has shown that our genetic code is similar to those of creatures such as worms, flies, weeds, and mice. This indicates that we are all descendants of a

single organism that emerged 4 billion years ago, supporting the evolutionary theories of Charles Darwin and the notion of evolutionary process as a constant reworking or random recombining of parts.

All living matter is made up of large molecules called proteins, which are mostly responsible for important functions absolved by cells, such as DNA processing, cell cycle regulations, and the production of auxiliary proteins that help proteins to take the correct shape, which is crucial for them to work properly. Proteins are constructed from 20 amino acids, and just as the letters of the alphabet can form words of various lengths and meanings, so different combinations of amino acids form specific proteins. Moreover, those parts of protein molecules concerned with carrying out similar functions in different organisms often have the same sequences of amino acids.

As far as cellular organization is concerned, the main chemical processes of all living matter (humans, animals, plants, fungi, or bacteria) are often identical. In 2001, the Celera Genomics team compared the human genetic code with that of organisms such as a fruit fly and a nematode worm. Its data suggest that humans and flies shared 2,758 genes, while there were 2,031 genes in common with the worm and 1,523 in common between all three. In addition 10% of the genes in humans were clearly shown to be related to particular genes in the fly and the worm. Comparing the human and the mouse genomes, the research concluded that only slightly more than 100 genes in the human genome do not seem to have a counterpart in the mouse genome.

The comparison of human and insect genomes points out, in the latter, the lack of genes associated with the immune system and of those associated with a circulatory system. The molecular machinery that manages programmed cell death appears to be much more complex in humans than in insects. The human genome also contains a marked increase in the number of members of protein families that are involved in nerve cell connections and development. Most significantly, humans have more genes associated with DNA and regulation. They come up to 12% of the human code, while they are only 8 percent of the insect

code. Yet these differences are simply variations on common themes. Thus, scientists have argued that the principle of the unity of life should inspire a sense of humility and respect for nature in all humans and challenge their supposed uniqueness.

LIFE, ORIGIN OF

One of the questions that has troubled humankind ever since it began to think about its position in the universe concerns its own origin and the origin of life in general. There are two basic alternatives for answering this question. Either we believe that life has a supernatural origin (such as being created by a transcendental God), or we think that the origin of life can be explained in a scientific way. This means that we try to describe an empirical scenario in which life originated through the workings of natural mechanisms. Here we are interested in the second alternative, but we must also say some words about the first one because the origin of life still is a problem about which religious, metaphysical, and scientific positions quarrel with each other.

Regarding the first alternative, speculating on a supernatural origin of life can be traced back to prephilosophical thought that is handed down to us by many orally transmitted and ethnologically collected myths of origin. The history of religions and metaphysics prolongs this mythical quest for origins. For example, the biblical Genesis reports that the world, all living beings included, was created by a personal God who himself is not part of his creation. Because the existence of such a transcendental creator is not an empirical fact that could be verified or falsified by scientific methods, the adequate cognitive attitude toward reports of creation like the biblical one is to either believe it or reject it for subjective reasons.

Nearly the same is true for metaphysical accounts of the origin of life. Metaphysics is a functional substitute of religion. It is the attempt of the human mind to develop a complete conceptual picture of the world that is structured by logical reasoning. To be complete, any metaphysical system must answer our question about the origin of life. The

speculative assumptions with which a metaphysics starts its reasoning are not of an empirical nature and impregnate all other metaphysical propositions with irrefutability because ad hoc explanations that agree with some metaphysical principle can be found anyway. Therefore, one must either believe a metaphysical system or reject it for subjective reasons that must be expressed in a coherent way.

For want of an empirical procedure of deciding which metaphysics is false, any metaphysical account of the origin of life, be it based on concepts such as entelechy (the Aristotelian tradition) or vital élan (the Bergsonian tradition), is not up to elementary standards of modern science that must be met if we want to follow the second way of answering the question about the origin of life: to describe an empirical scenario in which life originated by the workings of natural mechanisms.

Since the times of Galileo Galilei and Isaac Newton, modern science has searched for an empirically based and mathematically expressible description of all natural phenomena, its living inhabitants included. The aim is to acquire intersubjectively checkable and systematic knowledge of mathematical relations between empirical phenomena. Modern science approaches its aim by making controlled and replicable experiments with isolated natural systems. Of course, it also relies on hypotheses that are not themselves empirically verifiable (such as the supposition that nature can be described mathematically). Yet this is no drawback because, altogether, those hypotheses demand that any specific scientific proposition must be falsifiable by empirical data.

Any attempt to blur the boundary between religious belief and scientific doubt must be criticized. The result of mixing them up could only be a way of thinking that would lead to a religious ideology and a pseudoscience at the same time. It would let religious people lose the only legitimate source of their belief out of sight, and it would hinder science to follow its own dynamics of proposing and criticizing theories without ideological restrictions.

This is especially true when it comes to the origin of life. The empirical science that must find this origin is biology. Its general framework consists of evolutionary theory, which states that life is not a static phenomenon but rather a dynamic process. Life has a natural history; existing species die out, and new species are born. In the history of biology, different evolutionary theories gave diverse answers to the

question of how this process of speciation happens. Today, the evolutionary theory bearing the name of Charles Darwin is the theory that is accepted by nearly the totality of active biologists.

Since its second edition, Darwin's main work, *On the Origin of Species*, seems to give an answer to our question about the origin of life. This is no surprise because an evolutionary theory of life that takes into account the finite age of Earth must also explain the origin of life. But the famous last sentence of the book might be surprising because it states that the "several powers" of life have "been originally breathed by the Creator into a few forms or into one." Yet there is a plausible explanation for this religious stance. In the first edition, published in 1859, the prepositional phrase "by the Creator" was missing. Darwin added it to the second edition, published in 1860, because his secular account of the evolution of life suggested an equally secular explanation of the origin of life, but he did not want to bother his wife, Emma, who was a devoted Christian. Darwin himself was rather agnostically minded.

Scientific research on the origin of life tries to explain how the workings of physicochemical mechanisms led, in the boundary conditions of primitive Earth, to the development of material systems that possess necessary properties of life. Modern evolutionary theory assumes a natural continuity between the dynamics of prebiotic chemical systems and the evolution of the first living systems. It does invoke neither a supernatural principle nor some unknown natural force to explain the transition from the nonliving to the living. Older ideas of vitalism also proposed that the origin of life can be scientifically explained, but only if one also assumes the existence of some mysterious force that should be effective just in organisms. Because such a force was not found and even turned out to be unnecessary for explaining the structure and function of living systems, modern theories of the origin of life are reductionistic and mechanistic; they explain the origin of life exclusively by physical and chemical mechanisms giving rise to complex natural systems that we call "living."

One cannot get rid of our problem by proposing that life was imported onto Earth from some extraterrestrial origin, be it by chance (on an asteroid) or intentionally (by an intelligent extraterrestrial civilization). Wherever life appeared for the first time in the universe, its origin at that place must be explained. Although, according to the hypothesis of an outer

space origin of life (put forward by, for example, the English astronomer Fred Hoyle), life on Earth did fall from the heavens, the first of its extraterrestrial precursors could not do so. Thus, let us concentrate on the problem of how life originated on Earth without hoping that some extraterrestrial biologist will come to solve the problem for us.

The main conceptual prerequisite for answering our question involves a clear definition of life. This is not an easy task. We must combine necessary characteristics of living organisms in an evolutionary perspective. A modern biologist will specify at least three such properties. First, an organism has a biochemical metabolism. Second, it reproduces itself by transmitting genetic information to its descendants. Third, these descendants may differ from their parent because mutations and recombinations can occur in the transmitted genetic information. From an evolutionary perspective, these properties must be interpreted as features of systems that live in ecologies where natural selection occurs. The selective struggle for existence between such systems arises whenever a population of varying natural systems such as macromolecules or organisms self-reproduces under restrictions on growth.

Therefore, do we need not a single origin of life but rather as many origins as there are necessary characteristics of life? In this way, the physicist Freeman Dyson proposed that we must accept two separated origins of life: the origin of metabolism and the origin of self-reproduction. Of course, one could add the origins of other defining characteristics of primitive

organisms such as having some kind of membrane. The more we know about the necessary structural elements of early life forms, the more origins we get—until we have a sequence of many origins of life. But then we must ask what the first origin of life was. So we are back again at the very same point from which we started.

We do not need, however, to follow this line of thought. The previously mentioned characteristics of life are not standing separately next to each other. There is, for example, no simple dualism between information-based replication and biochemical metabolism. The behavior of an organism—made energetically possible by its metabolism—aims, after all, at transmitting the genetic information that is needed to construct the structural prerequisites for metabolism. Because of this causal and functional dependence of metabolism on genetic information, we must assume that the origin of genetic information is identical to the origin of life. The origin of life is nothing other than nature's first discovery of information processing via codes, that is, the evolutionary establishment of a primeval language. We are able to integrate mutability into this overall picture as well because the replication of genetic information in real chemical systems is often incorrect.

If the origin of life is identical to the origin of genetic information, can we infer that the origin of genetic information is the origin of deoxyribonucleic acid (DNA)? It seems so because molecular genetics describes inheritance as a complicated dynamics of storing, transmitting, processing, and transforming information where DNA acts as the material carrier of genetic information from parents to offspring. But the case is not so simple. According to current knowledge, there was a ribonucleic acid (RNA) world before the DNA world of today. Nowadays, the different types of RNA play important roles in the cell (such as transferring genetic information out of the nucleus in eukaryotic cells), but they do not act as the material carrier of the genetic information flow from parents to offspring.

The assumption that there was an RNA world solves an important evolutionary problem. To reproduce genetic information, proteins that act as catalytic enzymes in this process are needed. To produce such enzymes in a cell, their structure

Source: Courtesy of Wikipedia.

must be encoded in genetic information. To have this information in a cell, it must be copied before in the ancestor cell. To reproduce genetic information, those enzymes are needed and so on. RNA breaks out of this circle because RNA can store information in the sequence of its building blocks and catalyze its own replication enzymatically.

What is more, the biologist must also take into account the possibility that there was a precursor, or even a sequence of precursors, of RNA. The detailed chemical structure of such primeval information carriers is not known. Therefore, experimental research on the origin of life is of utmost importance. After a theoretical prelude during the 1920s (Alexander Oparin and J. B. S. Haldane), this kind of research started during the 1950s with the famous experiments of Stanley Miller and Harold Urey, who were able to synthesize, in a laboratory simulation of the atmosphere of primitive Earth, a multitude of organic compounds such as purines and pyrimidines (the bases that are components of the fundamental building blocks of RNA and DNA) and amino acids (the building blocks of proteins). Since Miller and Urey's experiments, great progress has been made in experimental research on the origin of life. One could especially note experiments with viral RNA, which self-replicates in a test tube without any surrounding cell so that one can start a selective evolution of information-bearing macromolecules in the laboratory (Sol Spiegelman).

In spite of this experimental progress, until now no biologist could experimentally reconstruct the historical origin of the first life form on Earth. It is even probable that we will never be able to simulate the real history of the transition from the nonliving to the living on primitive Earth. This impossibility can have two reasons.

First, one might suppose that the origin of life was a single event that happened against all odds. Because there are so many possibilities of how to combine all the compounds that are necessary for the spontaneous assembly of the first self-replicating macromolecule, it seems to be *a priori* very improbable that they all came together in the right concentration at the same place and at the same time (Jacques Monod). If life originated in such an extraordinary moment of absolute randomness, it is a realistic assessment that we cannot reproduce it in the laboratory because we would need to simulate successively an unforeseeable number of those possible chemical scenarios.

Yet the idea of a random origin of life underestimates the role of law-governed dynamic processes that can lead, from a diverse set of initial conditions, to the origin of life in many possible courses of natural history. But even according to this second conception, it is rather probable that the real primeval history of life will never be reconstructed in all details. We do not have enough information about the concrete circumstances of the transition from prebiotic to biotic evolution. So we can define only the class of possible histories that could have led to this transition. To do so, we must apply to the origin of life the very same theoretical idea that is used to explain the origin of species—natural selection.

How can we extend the Darwinian logic from biotic to prebiotic evolution? First, we must show how a set of chemical compounds can self-organize into a self-replicating system of macromolecules. For example, let there be three different kinds of macromolecules: A, B, and C. Now imagine that the rate of self-replication of B is proportionally dependent on the concentration of A, the rate of self-replication of C is dependent on the concentration of B, and the rate of self-replication of A is dependent on the concentration of C. So we get a closed cycle of macromolecules that depend on each other to maximize their rate of replication. As such, a cooperative structure, called "hypercycle," arises (Manfred Eigen and Peter Schuster).

Second, we must realize that such hypercycles are systems that self-reproduce (by reproducing their components cooperatively), have a metabolism (by importing the building blocks of their components and energy from their environment), and are mutable (by changing the structure of the components due to, as an example, the thermal movement of the involved molecules). In sum, hypercycles show all the phenomenological characteristics that are necessary for calling a system "living."

Third, we must see hypercycles as self-replicating and varying systems from a Darwinian perspective. In a common prebiotic ecology on primitive Earth, they would act as selective units that struggle against each other for chemical and energetic resources. As such, a process of natural selection among hypercycles would start, so that we are encouraged to call them "living" even from an evolutionary point of view.

Fourth, we must connect this rather formal model with our considerations on the first material carriers of genetic information. In a hypercycle, a nucleic

acid—be it RNA or some precursor—could reproduce autocatalytically. Of course, it would not store information about how to construct something other than its own structure. But if there arises some code by which the nucleic acid can control the synthesis of other macromolecules such as proteins and which helps to better replicate its chemical structure, our hypercycle would enter the next evolutionary phase of natural information processing. If this happens, our information-theoretical criterion of life would be fulfilled; it would identify the origin of life with the origin of genetic information, which is based on a code.

By elucidating even the origin of life, Darwinism shows its explanative power. Abstracted from the struggle for existence between macroscopic organisms and applied to the level of microscopic molecules, the Darwinian logic of variation, inheritance, and selection can explain the origin of prebiotic self-reproducing systems, which are the very first ancestors of what we are—macroscopic organisms.

If we accept Darwinism as an explanation of the past origin of life on Earth, we are urged to look into the future and to ask whether there could appear new forms of life—via new types of genetic information—by the same mechanism of Darwinian selection. This might occur not in the chemical ecology of our ancestors but rather in complex computer systems, where varying self-replicating programs could fight against each other for the resources of an electronic ecosystem without being controlled by some human programmer.

LINEAGE SYSTEMS, SEGMENTARY

Segmentary lineage systems are a form of decentralized and egalitarian social organization consisting of nested groups vested with the responsibility for security, defense, and welfare. Lineage systems are characterized by groups defined by descent from a common ancestor. Small groups trace their descent to close ancestors, whereas large groups (encompassing many small groups) trace their descent to distant ancestors. For groups to be discrete and not overlapping, descent is traced unilineally—through one line, either male or female. Patrilineages trace through the male line and are dominated by male and female descendants of the common male ancestor; matrilineages trace through the female line and are dominated by male and female descendants of the common female ancestor. In patrilineal systems, only males pass on group membership to their children; women's children are members of their fathers' groups. Conversely, in matrilineal systems, only females pass on group membership to their children; men's children are members of their mothers' groups.

Lineage systems are segmentary in that each group takes the same form as every other group, whether large or small, with each segment being like every other. These segments are organized in relation to one another into a balanced opposition. This organization is based on the general principle that genealogically closer groups unite in opposition to more distant groups and on the contingent nature of these groups by which they are activated only in situations of opposition to groups of structural equivalence and equal size. For example, if two men who are members of minor lineages in the same tribal section fight, only the members of each minor lineage are involved, but if members of two different tribal sections fight, all members of each section, regardless of minor lineage membership, are involved and, if mobilized, are acting as section members.

Segmentary lineage systems are important because in many tribal societies lineage groups based on descent through the male line are vested with important economic and political responsibilities. In segmentary lineage systems, patrilineages commonly have collective ownership of, or particular claims on, important resources such as land and water sources. In general, lineages are responsible for security, providing the defense force and undertaking collective

responsibility for gaining restitution or taking vengeance for losses and injuries. The original and most famous description of these systems, *The Nuer*, described a pastoral tribal people living in the southern Sudan. Edward Evan Evans-Pritchard recounted the correspondence between the lineage system and the territorial system that made possible their functioning as a decentralized, egalitarian, and expansionist political system. These systems are widespread in Africa (Somali, Libyan Bedouin) and in the Middle East (Turkmen, Arabian Bedouin, Baluch).

Segmentary lineage systems are best understood as means of defense and social control. The balanced opposition serves as a deterrent to aggressive adventurism. Collective responsibility of group members for each other guarantees that no individual or small group is a free target. Loyalty to one's lineage is not so much a sentimental attachment to blood kin as it is a hardheaded recognition of who one can count on when one gets into trouble.

Segmentary lineage systems are found where tribal political organization is possible. These systems provide security for life and property where important property, such as livestock and wells, need constant protection. They are also found where non-territorial means of relating people are useful such as among pastoral nomads, where people are frequently moving around and mixing. Under strong states, segmentary lineage systems are suppressed as competing powers.

LINGUISTIC RECONSTRUCTION

One of the most important tasks of historical or comparative linguistics is to try to establish a relationship between or among two or more contemporary languages based on a supposed common ancestry. The tool most often used to do this is linguistic reconstruction.

In 1786, Sir William Jones, a British judge and swashbuckling scholar who some more recently have compared to his namesake Indiana (in the *Indiana Jones* films), made a startling discovery: “The Sanskrit language . . . is of wonderful structure; more perfect than Greek, more copious than Latin . . . yet, bearing to both of them a stronger affinity, both in the roots of verbs and forms of grammar, than could have possibly been produced by accident; . . . [they] sprung from a common source which, perhaps, no longer exists.” What Jones was suggesting then was that Greek, Latin, and Sanskrit all shared a common ancestor in the distant past, just as three sisters might share a common grandfather. The reconstructed language is called a protolanguage, and reconstructed words or parts of words are called protoforms. (A protoform is usually preceded by an asterisk to distinguish it from actual speech.)

In doing a comparative reconstruction, word lists of the languages thought to be related are carefully compared to find cognates—words that share similar structures and meanings. For example, consider the following words for *sun* in four Native American languages: *hasi*, *hashi*, *haasi*, and *hasi* in Koasati, Choctaw, Hitchiti, and Creek, respectively. Ignoring the “long” *a* vowel in Hitchiti, what might the protoform for *sun* have been in the parent language? All of these words begin with the same sound, *h*, and use the low central vowel, *a*, so the word in the protolanguage probably contained these as well. But what about the *s* and *sh* sounds? By the “majority rules” strategy, we would argue that *s* was the original sound and that Choctaw underwent a change to *sh* for some reason. Thus, we would probably posit the protoform in this

protolanguage—actually called Muskogean by most Americanists—to be **hasi* rather than **hashi*.

But there is another reason why **hasi* is the more likely candidate. The “phonetic plausibility” strategy says that the sound changes we hypothesize must make sense phonologically based on our knowledge of how the speech organs operate. There is much world-wide linguistic evidence where an *s* sound becomes palatized (i.e., the tongue moves back toward the hard palate in the roof of the mouth) when it comes before a high vowel *ee* (the last vowel in all of the Muskogean words mentioned previously). There are few, if any, examples of the opposite; in other words is it more likely that an *s* becomes a *sh* than an *sh* becomes an *s* in this context. Thus, if a native English speaker is tired or drunk and wants to say the sentence “I didn’t see she was home,” the speaker would be more likely to slur it as “I didn’t *she* she was home” than to slur it as “I didn’t see *see* was home.”

Although phonological reconstructions are the most publicized, reconstructions can also be made at the level of morphology (units of words) and syntax (grammar). In terms of linguistic reconstruction in general, the Indo-European language family probably has received the most attention. Besides shifts in sound changes due to formal regularities, more historical linguists are also investigating the sociolinguistic motivations behind them. Linguistic anthropologists, from the time of Edward Sapir onward, have used linguistic reconstructions to explain the movement, contact, and history of non-Western peoples and will no doubt continue to do so.

LINGUISTICS, DESCRIPTIVE

Descriptive linguistics is a subfield of linguistics that studies and describes language in structural terms. In its investigation of linguistic structure, descriptive linguistics emphasizes the primacy of speech, the adoption of a synchronic approach, and the description of language and dialect systems as they are found to be spoken.

Descriptive Linguistics as a Scientific Pursuit

The rise of descriptive linguistics is generally attributed to the work of Ferdinand de Saussure (1857–1913), a Swiss linguist who is credited as being the father of modern linguistics. In the *Cours de linguistique générale*, a collation of his lecture notes published posthumously in 1916, Saussure laid out the general principles and methods of what has come to be known as descriptive linguistics.

The primacy of speech. Fundamental to Saussure’s teachings was the dichotomy of *parole* (speech) and *langue* (language). Language is a system of rules and conventions shared by a community of speakers, whereas speech is individual and particular utterances. The descriptive linguist uses speech to construct the underlying common structure or system of a language. In the construction of the language system, speech is primary and writing is secondary. Not only is speech older, but all writing systems are based on units of speech, yet no writing system captures all of the information that is carried in speech by variations of pitch, stress, gesture, facial expressions, space manipulation, context, and so on. There is also an overwhelming majority of languages that do not have a writing system. The primacy of speech, however, does not negate the importance of writing where homophony makes speech ambiguous, writing is completely independent of speech (Latin), or speech and writing have diverged significantly (Cantonese, Mandarin).

Synchronic approach. Descriptive linguistics is also known as synchronic linguistics. The synchronic study of a language involves describing it at a particular point in time without recourse to historical information. In contrast, the diachronic study of a language involves describing its historical development

through time. Diachronic description is based on the knowledge of previous synchronic states through which languages have passed historically. By necessity, synchronic description (descriptive linguistics) is prior to diachronic description (historical linguistics). This primacy of synchronic description also implies that diachronic information is irrelevant to the investigation of a language in a temporal state. To illustrate this point, Saussure used a famous analogy that compared languages to games of chess. The pieces of a chess set may be made of wood, ivory, onyx, metal, or something else. A treatise on the origins of the chess pieces or on the history of materials used to make them may be interesting, but it has no bearing on the understanding of chess games. What is crucial for an understanding of chess games is to know the synchronic relations among chess pieces. Equipped with this knowledge, the state of the chessboard at any particular time can be described without recourse to the previous combination of moves that has brought the game to that point. Similarly, any language can be described without recourse to information about its previous states. Unlike historical linguistics, descriptive linguistics is interested in all languages, not just those languages whose historical changes are known.

Descriptivism versus prescriptivism. Descriptivism is the policy of describing a language as it is found to be spoken. Descriptive linguists write rules and grammars to capture the knowledge that speakers have of their language in producing speech. The end product is a descriptive grammar, a model about how people speak and what they know of their language unconsciously. For Saussure, the goal of linguistic analysis is to uncover out-of-awareness native knowledge, a *langue* as opposed to *parole*. Prescriptivism is the belief that people must conform to the rules laid down by prescriptive grammarians and that deviation is corruption. A prescriptive grammar dictates how people should speak. It is not unusual that prescriptivists condemn utterances that appear to be perfectly normal to the majority of speakers, for example, “It’s me” instead of the prescribed form “It’s I.” Language change is the worst enemy of prescriptivism.

Structuralism. Saussure saw language as “a system of relations.” To analyze the structural importance of relations, he developed a number of dichotomies, including the famous syntagmatic–paradigmatic

dichotomy. Syntagmatic relations are contracted between units that can co-occur, whereas paradigmatic relations are contracted between units that may substitute for each other. The Saussurean point that linguistic units have no validity independent of their syntagmatic and paradigmatic relations with other units is well taken. With contributions like this, Saussure made the structuralist approach explicit for the study of language. It was Leonard Bloomfield (1887–1949) who propounded a general theory of language structure. Not only did his *Language* contain a thorough theoretical excursion, but the 1933 book also mapped out a detailed methodology for analyzing all levels of linguistic structure up to syntax. At the heart of Bloomfield’s theory is the autonomy of language, a thesis stating that the patterns of language operate with regularity and constitute an object of scientific study in its own right. Edward Sapir (1884–1939) and Bloomfield were the first two leading linguists of American structuralism to emphasize the importance of a descriptive approach to the study of language. They developed a substantial agenda for the autonomous, synchronic, and structural description of languages.

Discovery Procedure

The goal of descriptive linguistics is to “discover” a grammar by performing a set of operations on a corpus of data. The levels of grammatical description are to be arrived at in the following order:

1. Phonetics (speech sounds)
2. Phonemics (phonemes and allophones)
3. Morphemics (morphemes and allomorphs)
4. Syntax (sentence construction)
5. Discourse (use of speech)

This discovery procedure typically leads to the generation of three descriptive studies: a grammar, a dictionary, and an edited volume of texts in the language.

Descriptive linguistics features a rigorous application of basic concepts and analytical procedures. The basic units of analysis (for example, phone, allophone, phoneme, morpheme, allomorph, immediate constituent) are carefully defined, and the analytical procedures or *modi operandi* are laid out. The resultant descriptions are characterized by a systematic

exposition of the phonemes of the language, their phonetic variants (allophones), and their realization in the morphemes (morphonemics). This is followed by a treatment of the morphology and syntax of the language that is no less rigorous and systematic. By focusing on the shared structural features cross-linguistically, descriptive linguistics enables the classification of the world's languages typologically.

There is also a procedural constraint against “mixing levels.” As was shown earlier, in terms of analytical levels, phonemics precedes morphemics. Therefore, morphemes are to be discovered only after the phonemes of which they are composed are isolated from the data of speech. Moreover, morphemic or syntactic information must not enter a phonemic description. All of this is designed to ensure the scientific rigor of linguistic analysis against circularity. If two fairly bright graduate students who are trained in descriptive linguistics at two different institutions are sent out to describe an unanalyzed language at two different times and using two different informants, chances are that their analyses would be highly similar.

What has been presented is a “working up” model. It starts with the identification of speech sounds and phonemes and goes progressively up to examine how they are arranged into meaningful units (for example, morphemes, words, phrases) and what rules are used to combine these units into longer sentences and utterances. Conversely, the larger units of speech can be taken as the starting point as in the generative tradition. Sentences, for instance, are elicited directly and then broken down progressively. This “working down” model, however, is not what ethnographers usually follow in fieldwork. Because ethnographers must learn to speak the native language for participant observation, they tend to work up, beginning with the minutiae of the language, uncovering its structure bit by bit, and in the process managing to use its rule systems and everyday speech as a valuable source of insight into the culture of that speech community.

Descriptive Linguistics and Anthropology

Descriptive linguistics received its formative impact from anthropology as much as from linguistics. It was Franz Boas (1858–1942), the father of American anthropology, who set the stage for the development of a modern linguistic science in the United States. He developed a scheme for the systematic description

of languages and outlined it in the introduction to the *Handbook of American Indian Languages* (1911–1922). The scope of description envisaged by Boas was to include the psychology of meaning expression in addition to linguistic structure. In 1917, he founded the *International Journal of American Linguistics*, which was devoted to the descriptive study of the American Indian languages.

The history of American linguistics since Boas's groundbreaking impact is the history of the influence of Sapir and Bloomfield. As a student of Boas at Columbia University, Sapir was trained in anthropology. Like Bloomfield, he switched to the study of synchronic linguistics after doing brilliant work in historical linguistics. Whereas Bloomfield focused on the Algonquian languages around the Great Lakes, Sapir's principal work was with the native languages of the western United States and Central America such as Kwakiutl, Chinook, Yana, Wishram, Wasco, Ute, Nootka, Nahuatl, Chenyenne, Yurok, Comox, and Navajo. Sapir was perhaps the greatest fieldworker in the history of linguistics. The analyses of a number of American Indian languages that he presented have remained valid to this day. Especially noteworthy is his Takelma grammar of 1911 (published in 1922), in which he worked out the basic principles of structuralism before Saussure's *Cours* was published.

During the 1930s and 1940s, one of the primary concerns of descriptive linguistics was phonemics, which involves the classification of phonemes. Consider the *p*-like sounds in the words *pray* and *spray*, which are grouped under the same phoneme *p* in English. Acoustically, however, these *p*-like sounds are different, with one being aspirated and the other being unaspirated. Although this variation of aspiration is ignored phonemically in English, it is important in languages such as Sandhi because it gives rise to two different phonemes: an aspirated *ph* and an unaspirated *p* that differentiate meaning in words, as in *pTMnu* (snake food) and *pTMnu* (leaf). Conversely, where English speakers distinguish between the sounds *p* and *b*, as in *peach* and *beach*, speakers of Arabic do not and group *p* and *b* under the same phoneme. The list of examples can go on and on.

Difficulties arose when efforts to provide an object basis for defining the phonemes of an unknown language in face of their variation in sounds were attempted. A breakthrough came when Sapir proposed that the phoneme was a psychological unit under

which the native mind grouped a number of similar speech sounds (allophones). It was shown that the grouping of allophones into distinctive phonemes varied from language to language. Therefore, one could not impose the forms of one's own language on other tongues. Rather, each language had to be studied in its own terms and categories. Principles like these enabled the descriptive linguist to overcome the ethnocentrism to which Boas had objected.

Sapir also believed that linguistic structure had an underlying mental reality. To put it in Boas's words, language was the window of the mind. This belief was reinforced by the discovery that both the phoneme and morpheme were psychologically real and could not be explained away merely in behavioral terms. It led Sapir to assume that linguistic structure also played a role in shaping people's perception of reality, an idea that was mentalist and further developed by his student Benjamin Lee Whorf (1897–1941).

Bloomfield instead insisted on an empiricist orientation that allowed only statements based on direct observation or generalizations that were derived from observables. During his later years, Bloomfield was known for his stark refusal to consider semantics or mentalism as a part of linguistic science. It was his belief that neither could be studied scientifically. Under the predominant influence of Bloomfield's empiricism, descriptive linguistics came to focus on the internal structure of language without reference to meaning or psychology.

The descriptive linguist tends to rely on "direct elicitation" in data collection. To the extent that direct elicitation requires a native informant to reflect on language context free to a nonnative speaker (the field-worker or researcher), biases are inherent in the data collected. Some of the biases arise from decontextualized unnatural uses of language in elicitation sessions. Others are due to the fact that the informants may use simplified speech, such as "foreign talk," to cope with the abstract unnatural tasks imposed on them. Participant observation provides a remedy in that regard by helping the field-worker to observe native speech in context and to relate it to the meaning system and cognitive patterns of the native culture.

Descriptive linguistics has proved to be productive in the hands of linguistic and cultural anthropologists who retain the mentalist outlook of Sapir. Led by Morris Swadesh, Stanley Newman, Mary Haas, and C. F. Voegelin, they are responsible for the many careful

descriptive studies of American Indian and other indigenous languages that have been published and continue to be published. It is important to include the study of linguistics in the basic training of anthropologists. The insight that structural linguistics provides into the rule and meaning systems of language is indispensable for anthropologists attempting to examine language in broad terms.

LINGUISTICS, HISTORICAL

Historical linguistics is a subfield of linguistics that studies language in its historical aspects. It investigates a language or languages at various points in time. The term "diachronic linguistics" is often used in place of historical linguistics and sets it apart from "synchronic linguistics," which studies language at a single point in time. The investigation of historical linguistics involves language change, reconstruction, and classification.

Linguistic Change

No language stands still so long as it is spoken, and every language is the product of change. Linguistic change is cumulative and, for the most part, gradual enough to escape our attention as it occurs. Typically,

the cumulative effect of linguistic changes makes itself felt after a span of centuries. The longer the span, the greater the changes that are accumulated.

External Change

One way in which languages change is through the influence of other languages or *external change*. Such influence is most obvious in the borrowing of words that may arise from contact brought about by navigation, trade, cultural exchange, political dominance, conquest, and so on. The study of linguistic borrowing is often called “areal linguistics.”

The two principal strategies of lexical borrowing are loanwords and loan translations. A loanword is a word of foreign origin that is adapted at least partly in sound or grammar to the native ways of speaking. The English word *macaroni*, for instance, was borrowed from Italian (*maccheroni*). In loan translation, the parts of a foreign expression are translated, producing a new idiom in the native language, as in the French *gratte-ciel* and the Spanish *rascacielos*. Both are derived from the English word *skyscraper* and formed after the metaphor of “scraping the sky” to convey the idea of a very tall building. Such forms are a kind of calque in which the internal structure of a foreign expression is maintained but the morphemes are nativized.

Loanwords often have a life that cuts across the boundaries between languages. A case in point is the English word *chess*, which was borrowed from Old French during the 13th century. But the word originated in Persian and was adopted as a loanword by Arabic and then by Latin from Arabic. The Medieval Latin *scaccus*, in turn, gave the Old French *eschex* (singular *eschec*). Thus, the etymology of *chess* reaches from Persian through Arabic, Latin, and Old French to English.

The distribution of loanwords is a subject of serious study because it bears on the nature of contact between two languages during a particular historical stage. Consider what happened after the Norman Conquest of 1066, which made French the language of the official class in England. It is small wonder that many English words having to do with government, administration, nobility, law, military and religious affairs, and so on are of French origin. But when the English cow, sheep, pig, and calf were served at the table, they became the French *beef*, *mutton*, *pork*, and *veal*, respectively. French names were also given to the

culinary processes whereby the meats were prepared for Normans’ consumption.

Phonological and syntactic borrowing occurs less freely than does lexical borrowing. This is because a phonological or syntactic system consists of an integrated sum of rules, and the modification of one rule may have serious consequences elsewhere in the system. But there are known examples of phonological and syntactic borrowing. Old English (450–1100), for instance, did not have phonemes such as /v/ (*vase*), /z/ (*zeal*), and /Δ/ (*they*). It was with the introduction of loanwords from French as well as Latin that these three sounds eventually achieved phonemic status during the Middle English period (1100–1450). A well-known case of syntactic borrowing is the restricted use of the infinitive by the languages of the Balkan Peninsula (Albania, Bulgarian, Greek, and Romania). This shared trait is attributable to mutual borrowing instead of genealogical relationship that is quite indirect among them.

When two languages come into contact, linguistic acculturation ensues, resulting in the adoption of linguistic traits from each other. If the speakers are equally powerful or prestigious, we have two adstratum languages. In an adstratal relationship, linguistic borrowing goes in both directions, with each language serving as donor and recipient. If the speakers are unequal in terms of power or prestige, the language of the dominant group is called the superstratum language and the language of the less dominant group is called the substratum language. In this case, borrowing is primarily unidirectional, with the superstratum language serving as the donor and accepting only a few loanwords from the substratum language.

Linguistic borrowing is subject to sociolinguistic and structural factors. Traditional wisdom is that the degree of typological and structural similarity is more significant in determining whether an indigenous language accepts loanwords. Recent studies, however, have shown that the opposite is more likely to be true. In the case of Native American languages, for instance, past bilingualism appears to have been a more prominent factor in influencing the borrowing of lexical items and grammatical features.

Internal Change

Internal change can occur on all levels of linguistic structure. The difficulties that Middle English (1100–1450) poses for the modern reader, for instance, are due partly to the strangeness of outdated spelling

conventions. This was about to change when Geoffrey Chaucer (ca. 1340–1400) condemned what he considered to be haphazard variations in English vowel pronunciation. In actuality, these seemingly random variations were part of an internal sound change (the Great Vowel Shift) that resulted in the transition of Middle English to Early Modern English (1450–1700). Consequently, the spelling conventions of Shakespeare’s time were brought more in line with what we have today, but in an actual performance of a Shakespearean play the pronunciation of the actors is still not easy to follow.

Interestingly, internal sound change may be related to culture change. The distribution of *f* sounds in time and space, for instance, led Charles F. Hockett to propose in 1985 that as a relatively recent innovation attested by diachronic and synchronic evidence, the *f* sounds arose in association with agriculture. Not only is there a correlation between the development of *f* sounds in language and the practice of crop raising, but the use of cereal grains in the daily diet may have been responsible for inducing the changes in the dental configuration and jaw motion that made the articulation of labiodentals possible and easy.

Another form of internal change involves the loss and addition of lexical items. There used to be, for instance, an English verb *cennan*, meaning “give birth to,” but it has completely disappeared from the language. The addition of new terms can be through coinage (for example, *Kodak*, *xerox*), derivation (use of prefixation, use of suffixation), compounding (*takeoff*, *headstrong*), abbreviation (*radar*, *ASAP*), clipping (*exam*, *dorm*), blending (*brunch*, *smog*), functional shift (*to bag*, *to milk*), semantic change, and so on.

On the syntactic level, internal change may occur in word order or the use of morphemes that indicate syntactic relations among words. During the early stages of English, for instance, a possessive pronoun tended to follow rather than precede the noun it modified. Therefore, the Lord’s Prayer used to begin with *Fȝder ūre* (“Father our”) in the opposite order from what is said today. Even more dramatic is the amount of inflection shed by Modern English. Old English was a highly inflected language, employing an abundance of grammatical endings to distinguish case, number, gender, person, tense, and so on. In Modern English, however, there is relatively little left in the way of inflection. This revolutionary change was initiated by the lowly English peasants and shepherds, who adhered to their native tongue during the

Norman Conquest and, in the process, introduced an overhaul of the structure of English in their speech.

Reconstruction

The emergence of modern linguistics is often traced back to 1786, when Sir William Jones (1746–1794) published an article describing the structural similarities that crystallized from a comparison of Sanskrit, Greek, and Latin and called for the *reconstruction* of their ancestor language. At its onset, modern linguistics exhibited a predominantly *comparative historical* orientation.

The Growth of Comparative Historical Linguistics

Following the lead of Jones, the 19th-century historical linguists made a concerted effort to study the relationship among languages, especially those that constituted the Indo-European family of languages. Among these linguists were Rasmus Rask (1787–1832), Jacob Grimm (1785–1863), Karl Verner (1846–1896), and August Schleicher (1821–1868).

In 1818, Rask, a Danish linguist, wrote the first comparative grammar of the Scandinavian languages. Through rigorous comparisons, he mapped out the sound correspondences among these languages, brought order into their historical relationship, and defined their place in the Germanic branch of the Indo-European language family. Grimm, a German linguist, had focused his attention on the Germanic languages in general and Gothic in particular. His work resulted in two important achievements in 1822. One was the regular correspondences of consonants that he found between the Germanic languages, on the one hand, and Classic Greek, Latin, and Sanskrit, on the other. The other achievement was the revelation of the systematic nature of sound change. His conclusions went down as Grimm’s Law, a simplified summary of which is given as follows:

Indo-European				Germanic		
p	t	k	>	f	è	h
b	d	g	>	p	t	k
bh	dh	gh	>	b	d	g

However, there are exceptions to Grimm’s Law. Verner found that the regularity of the correspondences

predicted by Grimm was undercut by the place of the Indo-European stress. To account for the exceptions resulting from it, he proposed an additional phonological rule in 1875 that is to be applied to the outcome of Grimm's Law. The rule is named Verner's Law in honor of this Danish linguist.

During the mid-19th century, the German linguist Schleicher applied himself to the task of reconstructing the protolanguage of the Indo-European family. A protolanguage is a hypothetical parent language reconstructed from a group of languages that appear to be related. Schleicher set the reconstruction process on a solid footing by synthesizing the work of his precursors and formulating the "family tree theory" in 1871. According to this theory, language changes in regular ways (the regularity hypothesis) and similarities among languages are the result of a genetic relationship among them (the relatedness hypothesis). To reconstruct the protolanguage, the comparative method is to be used.

The Comparative Method

The technique of comparing related languages to arrive at a reconstruction of the protolanguage is known as the *comparative method*. It is a technique for establishing the relatedness of several languages and for reconstructing the linguistic forms (such as sounds, morphemes, words) of their protolanguage. In both cases, the comparative method works primarily with cognates.

Cognates are words that belong in different languages but are descended from the same ancestral root. A cognate set is a group of words similar in form and meaning. The English word *three*, for instance, is a cognate of Sanskrit *tri*, Persian *thri*, Greek *treis*, Latin *trēs*, German *drei*, Dutch *drie*, Icelandic *thrir*, Welsh *tri*, and so on. The application of the comparative method to this cognate set yields **treyes* as the proto-Indo-European form, where the asterisk (*) denotes its hypothetical nature. The sound correspondences revealed in this case also operate with regularity in other sets of cognates from these languages.

There is no intrinsic tie between form and meaning. This led Shakespeare to remark, in *Romeo and Juliet*, "That which we call a rose, by any other name would smell as sweet." If names are arbitrary, then the probabilities that different languages randomly choose to call the same thing by similar names are statistically insignificant. When we do find similarities (cognates), they are taken to point to relatedness. However, this is

on the condition that their resemblance is not due to chance or borrowing. For example, Modern Persian has a word that virtually sounds and means the same as the English word *bad*, but the Modern Persian sound correspondences (*b-b*, *ḡ-ḡ*, *d-d*) do not recur in a large set of linguistic items. It is relatively easy to eliminate chance similarities of this sort. Eliminating similarities due to borrowing, however, is more difficult. A common strategy is to focus on basic vocabulary, an area where borrowing has the least effect.

Given a cognate set, the historical linguist is able to arrive at its protoform by means of comparative reconstruction. The process involves examining each sound correspondence and applying two principal strategies. One is to reconstruct the sound occurring in the greatest number of languages being compared (majority rules), and the other is to reconstruct the sound that would have undergone the most common sound change (the rule of realism). In case there are two alternative analyses, preference is given to the one that is more natural or more explanatory in the sense that it sits better with the overall linguistic structure. No reconstruction, however, should violate the maxim of "Occam's Razor," which favors the simplest possible analysis. Following the reconstruction of the protoform, the linguist goes on to specify the sound changes that applied to the daughter languages and to check whether these proposed changes operated regularly across the whole collection of cognate sets.

Linguistic paleontology or archaeology uses reconstructed lexical items to recover information pertaining to prehistoric culture, society, and geographical facts. In the case of proto-Indo-European, linguistic evidence suggests that its speakers were small farmers who worked their fields with plows, had a clear sense of family relationship, kept domesticated animals and fowls, used wheeled vehicles, could count, lived in small villages, and believed in multiple gods. The original home of the Indo-Europeans must have been in an area of Central and Western Europe, defined by the coexistence of beech and birch trees. Similarly, the proto-Athabaskan kinship system seems to contain evidence that its culture featured bilateral cross-cousin marriage, de facto sister exchange, and sororal polygyny, among others.

Internal Reconstruction

The *internal reconstruction* technique is designed to reduce synchronic, language-internal variation to an

earlier stage of invariance. Except for majority rules, the strategies discussed in connection with comparative reconstruction are also applicable to internal reconstruction. In addition, the linguist is watchful for the effects of “conditioned” sound change in that they might cause morphological irregularities in inflectional and derivational paradigm. Consider the following data from Latin, where only item 1 contains irregularities:

<i>Singular Normative</i>			<i>Singular Dative</i>			
(1)	urp-s	urb-is	“city”	rēk-s	rēg-is	“king”
(2)	wōk-s	wōk-is	“voice”	stirp-s	stirp-is	“root”

Internal reconstruction will yield the protoforms **urb-s*/**urb-is* and **rēg-s*/**rēg-is* for item 1. A conditioned sound change caused the devoicing of **b* and **g* before voiceless *s* in the protoforms **urb-s* > *urp-s* and **rēg-s* > *rēk-s*, hence the synchronic irregularities. This process is known as “voicing assimilation,” but it had no effect on voiceless **k* and **p* in the protoforms of item 2: **wōk-s* > *wōk-s* and **stirp-s* > *stirp-s*. By recovering the protoforms and the conditioned sound change, internal reconstruction completes its reduction of synchronic variation to historical invariance. However, the application of internal reconstruction has limitations. After all, an earlier structural feature can be reconstructed only if evidence for positing it happens to have been retained.

Classification

The historical linguist seeks to classify the world’s languages in terms of genetic relationship. Such relationships are couched in the idiom of kinship so that a protolanguage is a parent language, with the divergent languages as its daughters and as sister languages among themselves. A parent language and its daughters constitute a genetic group or language family.

The most popular mechanism for diagramming genetic relationships is the family tree, a device created by August Schleicher. As can be seen in the figure, in its basic form, a family tree consists of a parent language (A) as a starting point, with branches showing the daughter languages (B–F).

This is reminiscent of a speech community splitting into dialectal segments that do not communicate with one another until they are mutually unintelligible and become separate languages. Once a dialect achieves

the status of a language, it is itself subject to the process of dialectal split and the ultimate generation of new languages. Each branching node in a family tree represents a formerly existing language that is ancestral to the languages branched from it.

Eurasia

An overwhelming majority of the European languages belong to the *Indo-European* family, which is divided into 10 branches. English is a member of the Germanic branch, as are Frisian, German, Dutch, Yiddish, Gothic, and the Scandinavian languages. The other branches are Albanian, Anatolian (Hittite, Palaic, Lydian, etc.), Armenian, Balto-Slavic (Latvian, Lithuanian, Russian, Serbo-Croatian, Polish), Celtic (Welsh, Irish, Breton, Scots Gaelic), Greek, Indo-Iranian (Sanskrit, Persian, Hindi, Bengali, Romany), Italic (French, Spanish, Italian, Portuguese), and Tocharian.

Eurasia is home to several other language families as well. Among them are *Caucasian* (Georgian, Avar, Kabardian), *Uralic* (Hungarian, Finnish, Lapp), *Altaic* (Turkish, Uzbek, Manchu, Tungus), *Sino-Tibetan* (Chinese, Burmese, Tibetan, Miao), *Dravidian* (Tamil, Telegu, Kannada, Malayalam), *Tai-Kadai* (Thai, Laotian, Kam-Sui), *Austro-Asiatic* (Santali, Mon, Khmer, Nicobarese), and *Palaeo-Siberian* (Chukchi, Koryak). There is a lack of consensus as to whether Korean and Japanese are members of the Altaic family or actually form a language family of their own.

Oceania

The languages of Oceania are grouped into four phyla (superfamilies). The *Austronesian* phylum, also known as Malayo-Polynesian, consists of some 900 languages that are spoken on the islands of the Pacific and Indian oceans from Madagascar off the coast of Africa to Malaysia of Asia. Some of the Austronesian languages are Malagasy, Hawaiian, Fijian, Samoan, Māori, Tagalog, Indonesian, and Malay. The indigenous languages spoken on the continent of Australia are grouped as the *Australian* phylum. Among the indigenous languages that have the most speakers are Tiwi, Walmatjari, Warlpiri, and Aranda. The much smaller island of New Guinea shows a tremendous variety of languages. Collectively, they are known as the *Papuan* phylum, which may contain a large

number of language families. Oceania used to have one more language family, *Tasmanian*, which is now extinct.

Africa

The languages of Africa can be classified into one of four phyla. The *Afro-Asiatic* phylum, also known as Hamito-Semitic, contains languages spoken in north and northeast Africa and the neighboring parts of western Asia. This phylum consists of five families. *Semitic* is the most widespread and includes Hebrew, Aramaic, Arabic, Amharic, and extinct languages such as Akkadian and Phoenician. The other four families all are restricted to Africa: *Berber* (Tuareg, Riff, Kabyle), *Cushitic* (Somali, Gala, Walamo), *Chadic* (Hausa, Gabin, Mandara), and *Egyptian* (Coptic).

Congo-Kordofanian is the largest language phylum in Africa, extending from the equator to the extreme south. *Kordofanian*, however, is a small group of languages spoken in Sudan. The division of *Niger–Congo* is vast and consists of six families. *Benue-Congo* is the most numerous, with some 700 languages, including the Bantu languages (Swahili, Zulu, Kongo, Rwanda) that are spoken throughout central and southern Africa. The other families are *West Atlantic* (Fulani, Wolof), *Mande* (Malinka, Bambara, Mande), *Gur* or *Voltaic* (Mossi, Tallensi, Nupe), *Kwa* (Yoruba, Igbo, Akan, Ewe), and *Adamawa-Eastern* (Sango, Gbaya).

The *Nilo-Saharan* phylum is a highly diversified group of languages that are spoken in three areas. One is around the upper parts of the Nile River, with languages that belong to the Sudanic branch. Another area lies to the east of Lake Chad and is home to the Saharan branch. The third area is spread along the

Niger River of Mali and is home to the Songhai branch. The best-known members of this family are Masai, Nubian, Kanuri, and Songhai.

Khoisan is the smallest language family, containing a group of languages spoken in areas scattered around the Kalahari Desert in southern Africa. Until fairly recently, speakers of Khoisan were foragers, known to the outside world by labels such as Khoikhoi, Hottentot,

Bushman, and San. Their languages feature the use of click consonants. Through borrowing, this distinctive feature has found its way into certain other African languages such as Zulu and Xhosa.

North America

In North America, the *Eskimo-Aleut* family is found in the extreme north. Eskimo languages are spoken on the Arctic shores of Alaska, Canada, and Greenland as well as along the tip of Siberia. These languages are linked to the native language of the Aleutian Islands that is virtually extinct. A relationship between Eskimo-Aleut and the Palae-Siberian family of Asia has been suggested.

Further south is the *Na-Dené* phylum, a grouping of languages spoken in the Pacific Northwest (western Canada and northern California) and the southwestern United States (Arizona and New Mexico). With a few exceptions, such as Haida and Tlingit, these languages belong to the *Athabaskan* family. Some of the main Athabaskan languages are Navajo, Beaver, Chipewyan, Dogrib, Hare, and Hupa.

The *Algonquian* family was found in central Canada and the Great Lakes region in association with a number of tribal languages (Ojibwa, Cree, Arapaho, Cheyenne, Micmac, Shawnee). Other major North American families include *Wakashan* in the Pacific Northwest (Nootka, Kwakiutl), *Salish* in western Canada and the western United States (Flathead, Squamish), *Iroquois* in eastern Canada and the eastern United States (Huron, Mohawk, Seneca, Cherokee, Tuscarora), *Siouan* in the Great Plains (Dakota, Omaha, Osage, Crow, Hidatsa), *Caddoan* in the southern Plains (Pawnee, Wichita, Caddo), and *Muskogean* in the

southeastern United States (Creek, Koasati, Choctaw, Muskogee).

Moreover, there are three language phyla that have an extensive north–south distribution. One is *Hokan*, which links the *Yuman* family in southern California with languages such as Tlapanecan and Jicaque in Central America. The *Penutian* phylum is a grouping of languages spoken in North and Central America and probably in South America as well. *Mayan* is its most important family, with Yucatan, Mam, Quiche, and Kekch'in continuing to be widely spoken today. The third phylum is *Aztec-Tanoan*, which had an impressive presence in the western United States and Mexico. Some of its languages are Ute, Paiute, Shoshone, Comanche, and Hopi as well as Nahuatl, Pima-Papago, and Tarahumar, which are still spoken in Mexico. Also included in this phylum are a number of Pueblo languages.

Oto-Manguean is the only phylum restricted to Central America. It consists of several diverse families such as Zapotecan and Mixtecan. Both the vicissitude of pre-Columbian civilizations and a mountainous topography may have contributed to the linguistic diversity of Middle America. Some of the languages in this area are grouped with South American families.

South America

The South American continent is linguistically diversified, with a total number of languages estimated to be between 1,000 and 2,000. Only some 600 South American languages are documented, and some 120 of them are extinct. These known languages are grouped into three major phyla.

The *Macro-Chibchan* phylum covers the north-west of the continent in addition to parts of Central America and certain areas in northern and western South America. Languages of this phylum include Chibcha in Colombia, Esmeralda in Ecuador, Rama in Nicaragua, Cuna in Panama, and Waica along the Venezuelan–Brazilian border. The second phylum is *Ge-Pano-Carib*, found in northern and central South America. *Ge* is a family of languages spoken in central Brazil; the *Panoan* family is concentrated in Peru, Bolivia, and Paraguay; and the *Carib* family is widespread in northeastern Brazil, Venezuela, and the Guayanas. The third phylum, *Andean-Equatorial*, extends from central South America to southern Argentina. Its most important language families are *Arawakan*, once spoken from the Antilles down to

Paraguay, *Tupi-Guarani*, whose speakers occupy a large portion of Brazil and most of Paraguay, and *Quechumaran*, which contains Quechua and several languages spoken in Argentina.

New Classification

The Amerindian languages, a new classification, are conventionally grouped into some 200 families. Various links of relationship between and within these families have been proposed. In a new world-wide grouping of languages proposed during the mid-1980s, Joseph Greenberg (1915–2001) held that the native languages of the Americas belong to just three phyla: *Eskimo-Aleut*, *Na-Dené*, and *Amerind*. Indeed, there is anthropological evidence that links the first two groupings to two late migrations from the Old World into the New World. The arrival of Eskimo-Aleut speakers was more recent and was predated by the arrival of Na-Dené speakers.

The idea that all other New World languages are derived from proto-Amerind has remained controversial. On the one hand, physical anthropology reveals substantial differences among the modern speakers of Eskimo-Aleut, Na-Dené, and all other American Indian languages. On the other hand, many scholars wonder how some 2,000 languages could have diverged from a single tongue within the span of 12,000 to 20,000 years since the earliest migration into the New World. The procedure generating the new classification of Amerindian languages is called “mass inspection.” It lists words by language for comparison, and when look-alikes cluster, an earlier genetic relationship is hypothesized. This process is based on the assumption that at remote time depths, regular sound correspondences will be lost and only residual cognates will remain.

Language Isolates

If a language has no known relationship to any other language and does not lend itself to assignment to a family, it is called an isolate. *Basque* is one isolate that is spoken in the region of the Pyrenees (southern France and northeastern Spain). Other well-known language isolates include *Adamanese* (islands in the Bay of Bengal), *Burushaski* (Kashmir and India), *Ainu* (northern Japan), *Fur* (Sudan and Chad), *Keresan* (New Mexico), and *Kutenai* (western North America). Some extinct languages are also considered isolates,

including *Sumerian* (Mesopotamia), *Iberian* (Spain), *Etruscan* (Italy), and *Mohenjo-Daro* (Pakistan).

LINGUISTICS, TRANSFORMATIONAL

Transformation grammar is a way of viewing syntax first proposed in 1957 by Noam Chomsky, the most influential linguist of the 20th century. It is hard to overestimate the impact this new theory had on all of the social sciences; within a few years, it had replaced the prevailing paradigm of structuralism in linguistics and behaviorism in psychology. Chomsky's method of explaining grammar is far-reaching and offers a unified view of the mind and human behavior.

Until the 1960s, stimulus/response-style behaviorism was at least tacitly accepted by an overwhelming majority of American psychologists (as well as by many working outside the field). Language was believed to be acquired through successive reinforcements of increasingly correct responses of a target item. Native English-speaking children, then, would go from saying *wa-wa* to *wata* to *water* because they

would receive more drinks the closer they came to the adult pronunciation.

Until the 1950s, linguists were usually concerned either with historical issues of reconstruction or philology or with formal methods of describing the structures of the world's languages. For example, much attention was paid to how constituents of words or sentences were organized hierarchically. Structural linguists could show why phrases such as “old men and women” were ambiguous (i.e., do we mean old men and *all* women or only old men and *old* women?) by dissecting them into their ordered component parts.

Chomsky showed the limitations of these approaches to psychology and linguistics. First, most infants are exposed more to baby talk than adult speech by their parents, yet most children learn correct forms. Second, Chomsky argued, because most people create new sentences they have never heard before, linguists need to focus their attention on how speech is generated rather than analyze forms already uttered. Chomsky posited a set of *phrase structure* or *rewrite* rules that outline how a basic sentence might be constructed in a language. For instance, in English we might define a rule whereby sentences are composed of (a) noun phrases as subjects (for example, “I”) and (b) verb phrases. A verb phrase (“ate”) can be rewritten as a pure verb plus a noun phrase direct object (“ate the hamburger”). Thus, a sentence such as “I ate the hamburger” could be made by these few simple rules. With the addition of a lexicon—a set of possible words that could fit into the various slots in a sentence—an infinite number of sentences could be generated.

However, most native English speakers intuitively feel that other sentences, such as “I did not eat the hamburger,” “Who ate the hamburger?,” and “The hamburger was eaten by me,” are somehow related to our initial sentence. Chomsky posited special transformational rules that formally derive these from the basic, or kernal, sentence. For example, a simple English passive transformation might be that if given a sentence of the form “X verbs Y,” we can create the well-formed sentence “Y was verb + past tense by X.” Thus, “Joe sees Jane” also allows us to say “Jane was seen by Joe.” The task, then, is to discover the right phrase-generating rules and all of the different transformations they entail.

Chomsky maintained that these kinds of rules, although specific to each language, are universal.

All languages, then, are really more alike than different. Besides changes in nomenclature, Chomsky's project has gone through several substantial revisions over the past four decades, including government and binding theory, principles and parameters, and the current minimalist program. However, transformation linguistics is still the dominant model in the language sciences (although certainly not without its critics). Thus, no linguists, anthropologists, cognitive scientists, psychologists, or philosophers have been unaffected by Chomsky's theories, even if they are not in full agreement with his claims.

LINNAEUS, CAROLUS (1707–1778)

Carolus Linnaeus, the originator of the system of classification of animals and plants that we still use today, was eventually ennobled in 1757 as Carl von Linné. He was born in southern Sweden during the first decade of the 18th century, a time when knowledge of exotic faunas and floras was beginning to seep into Europe as a result of mercantile voyages to remote parts of the world. Educated in medicine at Lund and Uppsala universities, he was steered early on into the study of botany by the Uppsala professor Olof Celsius.

From 1732 onward, Linnaeus undertook a series of botanical surveys in different parts of Scandinavia and also visited other parts of Europe, notably France, England, and Holland, where he completed his medical studies in 1735. That year, he also published the first edition of his great classification of nature, *Systema Naturae, Sive Regna Tria Naturae, Systemice Proposita per Classes, Ordines, Genera et Species*. Back in Sweden, in 1739 Linnaeus participated in the

founding of the Royal Swedish Academy of Science, in 1741 he assumed the chair of medicine at Uppsala, and in 1742 he switched that for the chair of botany. Over the next decade or so, he published a series of strictly botanical volumes while at the same time devoting himself to the enlargement and refinement of his encyclopedic *Systema Naturae*. This latter work eventually became his primary preoccupation and the source of increasing international fame, going through 12 editions before his death in 1778. For the purposes of priority in animal taxonomy, the definitive edition of *Systema Naturae* is taken to be the 10th, published in 1758. By international agreement, the correct name for any species is the one given it by Linnaeus in 1758 or the first one to be validly published after that date.

From an anthropological point of view, the most important aspect of the 10th edition is that in it

Linnaeus included the species name *Homo sapiens*, within which he formally recognized four “varieties”: “Americus,” “Europaeus,” “Asiaticus,” and “Afer” (essentially African). This was also the edition in which he changed the name of his class Quadrupedia to Mammalia and introduced the order primates to unite the genera *Homo*, *Simia*, *Lemur*, and *Vespertilio* (bats). Linnaeus’s notion of *Homo* still owed something to the ancient idea of the Great Chain of Being and included certain forms more appropriate to a bestiary, but it did group our own species in the same genus as *Homo troglodytes*, a construction essentially based on the orangutan. In classifying *H. sapiens* in the same genus as an ape, and this genus together with the lemurs and monkeys, Linnaeus took the bull by the horns and included humans as an integral component of nature.

The roots of Linnaeus’s system of classification go back to Aristotelianism and medieval scholastic logic with their entailed concepts of essence, but in practice the Linnaean approach has proved to be remarkably adaptable to changing biological perspectives. The 10th edition was published a century before Darwin’s *On the Origin of Species* introduced the notion of evolution into biological classification. But with a judicious expansion of rank levels, Linnaeus’s inclusive classificatory hierarchy, whereby species are grouped into increasingly comprehensive sets (for example, genera, orders, classes), actually fits the branching pattern of evolutionary descent quite well and is certainly preferable as a practical matter to the alternatives offered.

LINTON, RALPH (1893–1953)

Ralph Linton was an American cultural anthropologist known for his academic bravado and popular appeal, as well as for his long-lasting conceptual and

theoretical contributions to anthropology and social science in general, whose main interest was the relationship between culture and personality. One of his more established concepts was acculturation, a phenomenon he witnessed throughout his many travels, published on, and in a sense contributed to through his work for Columbia University’s School of Military Government and Administration, where he educated military personnel on the characteristics of extrinsic cultures. Along with Abram Kardiner, Cora Du Bois, and Edward Sapir, Linton was a founder of basic and modal personality structure theory, an interactional approach that challenged earlier, culturally deterministic theories of personality. Although he was not a physical anthropologist, Linton considered the differences between humans and apes—indeed, between humans and other animals in general—by and large trivial ones and ultimately pointed to biological influences as an important factor in understanding the origins and nature of human behavior and culture. He was the first to use the terms “status” and “role,” now staple social science concepts. Linton’s best known works include *The Study of Man* (1936), *The Cultural Background of Personality* (1945), *Most of the World* (1949), and *The Tree of Culture* (1955).

Linton was born in Philadelphia to a Quaker family on February 27, 1893. His father, Isaiah Waterman Linton, made a living through his ownership of a chain of restaurants. Isaiah and Linton’s mother, Mary Elizabeth, took an authoritarian and critical approach to rearing the young Ralph, making for a childhood that was less than ideal. After graduating from Friends High School, Linton pursued a B.A. at Swarthmore College, where one of his teachers encouraged him to study cultures outside his own. Although during his later years Linton would sometimes be criticized for not supporting his theoretical statements with empirical evidence, from the beginning he was anything but an armchair anthropologist. As an undergraduate, Linton interspersed his course work with (prehistoric) archaeological excursions to New Mexico, Colorado, New Jersey, and Guatemala.

Linton earned an M.A. from the University of Pennsylvania in 1916. He married his first wife, Josephine Foster, that same year and then went on to study at Columbia. When World War I broke out, and in violation of the pacifist principles by which he was raised, he left Columbia to join the army and saw combat in France. This caused him to be banned

from attending “Friends Meetings” (the Quaker equivalent of “church”). After the war, Linton returned to America and married his second wife, Margaret McIntosh, with whom he had one child. He then spent several years doing fieldwork in Polynesia, eventually leading to the publication of *The Material Culture of the Marquesas Islands* (1923).

His experiences in Polynesia represented a turning point for Linton. Realizing that he preferred interacting with living people to digging for artifacts, he shifted his focus from archaeology to anthropology. In 1922, Linton became assistant curator at the Field Museum of Natural History in Chicago, a position he held until 1928. He undertook an expedition to Madagascar for the museum in 1925, and for years thereafter he did a great deal of traveling on that island and in East Africa, managing to finish his Ph.D. at Harvard University around the same time (1925).

Linton’s academic career began at the University of Wisconsin–Madison when he accepted a professor’s position there in 1928. In 1934, after his second marriage ended in divorce, he married Adelin Sumner Briggs. It was at Wisconsin that Linton published what he considered to be his most important work. *The Study of Man* (1936) was an attempt to integrate diverse perspectives and findings in anthropology and related fields into one coherent treatise. Linton explicitly intended the book as a primer for beginning students, and it was used as an introductory text by anthropology departments for a period of time. *The Study of Man* ran the gamut of relevant topics, including human origins, formation of culture, basic social institutions, the birth of states from tribes, and personality. Praised for the qualities he intended, the book was also criticized for Linton’s failure to fully document many assertions.

Linton became a professor at Columbia in 1937, where he collaborated with Abram Kardiner, among others, to develop a new treatment of personality by anthropology (basic and modal personality structure theory). After coauthoring key works on the topic with Kardiner, Linton broke with his colleague and wrote *The Cultural Background of Personality* (1945), which reflected his independent take on the subject. In this book, Linton attempted to synthesize ideas from anthropology and personality psychology, and to a lesser extent sociology, toward the purpose of understanding the reciprocal relationship between culture and personality. He discussed several concepts for which he is known today, including status personalities and

value–attitude systems. Linton’s drive toward synthesis in *The Cultural Background of Personality* included a conscious attempt to create a standardized terminology for the fields in question.

The break with Kardiner illustrates the irony that Linton found he could live easily among the various cultures he studied, yet he experienced difficulties with relationships in his personal and professional life. In addition to being married three times, his tense rapport with colleagues sometimes turned stormy. Another colleague with whom Linton often butted heads was Ruth Benedict, who resented being passed over in favor of him as department head at Columbia. Ultimately, Linton left the university altogether over his academic disagreement with Kardiner.

In 1946, Linton was appointed Sterling Professor of Anthropology at Yale University, where he would finish his academic career. He died in New Haven, Connecticut, after a long period of health problems. His final book, *Tree of Culture* (1957), was written during his tenure at Yale but was published posthumously. Completed by Linton’s wife from materials and instructions left by her husband, the book relies greatly on a broad sampling of specific cultures studied by the author over his lifetime. Like *The Study of Man*, *Tree of Culture* was an attempt at grand synthesis. Culture, Linton argued, is a tree that grows not in the linear sense but rather more in the manner of the tropical “banyan tree,” the branches of which send roots back down into the ground, eventually to become trunks themselves. *Tree of Culture* was both criticized and praised for the same reasons as was *The Study of Man*. Indeed, a related criticism was that the books were not terribly different. Perhaps it would be best to say that Linton’s final work reflected the man himself—courageous, engaging, and, even if not perfectly pleasing to his colleagues, stimulating throughout for the intended audience.

RALPH LINTON

Ralph Linton was an American archaeologist, a cultural anthropologist, and a writer who made important contributions to the understanding of human culture. He has been described as a creative thinker who could unite disparate facts into a clear picture. His writings stimulated the popular imagination of anthropological work, but he often failed to fully document his writings.

Linton was born in Philadelphia in 1893. His name was originally spelled Rolfe after his famous ancestor, John Rolfe, the husband of Pocahontas.

Linton attended Swarthmore College in 1910. In 1912, he worked at Mesa Verde, New Mexico, on an archaeological dig. In 1913, he joined an archaeological expedition to Qirigu, Guatemala. In 1915, he graduated from Swarthmore, and that summer he excavated a prehistoric site in New Jersey for the University of Pennsylvania's museum. In 1917, he reported his findings in *A Pre-Lenape Site in New Jersey*.

In 1916, Linton received a master's degree in anthropology from the University of Pennsylvania. He then went to Aztec, New Mexico, to join an archaeological dig. During the fall of 1916, he began graduate work at Columbia University. He spent the early part of the summer of 1917 with an excavation group in southern Illinois. In August 1917, Linton joined the U.S. Army during World War I. He served with the 42nd (Rainbow) Division until the fall of 1919. In battle, he was gassed and wounded. Because of his war service, he was expelled from the group of pacifist Quakers to which he belonged.

Linton returned to Columbia in 1919 to renew his studies. In 1920, he went to the Marquesas Islands for the B. P. Bishop Museum of Honolulu, Hawaii, to conduct an archaeological survey. In 1925, Linton received a Ph.D. from Harvard University. That same year, he went to Madagascar for Chicago's Field Museum of Natural History to collect specimens and study the native life.

In 1937, Linton published *Study of Man*, an introduction to cultural anthropology for the general public. The success of *Study of Man* and subsequent publications led to his appointment as

the head of the anthropology department at Columbia. At Columbia, Linton published *Cultural Background of Personality* (1945). He also edited *The Science of Man in the World Crisis* (1945).

In 1946, Linton was appointed as the Sterling Professor of Anthropology at Yale University. In 1953, he died in New Haven, Connecticut. In 1955, his book, *The Tree of Culture*, was published posthumously.

LLANO CULTURE

Llano culture refers to late Pleistocene North American people on the Llano Estacado, or Southern High Plains, who used distinctive stone projectile points, known as Clovis points, to hunt mammoths. Formal description of the Llano culture during the 1950s established it as the oldest known prehistoric archaeological culture in North America and reinforced the notion that Paleoindians were specialized big game hunters. The term "Clovis culture" replaced "Llano culture" by the late 1960s, so Llano culture is primarily a historical concept important for its role in Paleoindian studies.

Elias H. Sellards proposed the term "Llano complex" in his 1952 book *Early Man in America* for assemblages of artifacts associated with mammoth (*Mammuthus columbi*) bones at archaeological sites on and near the Llano Estacado (Spanish for "staked plains") of western Texas and eastern New Mexico. The artifacts of the Llano complex consisted of distinctive stone projectile points, stone hide scrapers, hammerstones, and bone tools. Sellards used the terms "Llano culture" and "Llano man" to refer to the people who made and used the artifacts. Sellards included in his Llano complex sites throughout much of North America that contained Clovis points, regardless of whether they also contained mammoth remains.

Sellards was a geologist by training, but since 1915 he had pursued an interest in the antiquity of humans in North America. Not until the discovery in 1927 at Folsom, New Mexico, of distinctive stone projectile points (Folsom points) found in unambiguous association with bones of extinct bison (*Bison antiquus*) did it become generally accepted that humans had

been on the continent for more than a few thousand years. *B. antiquus* was thought to have gone extinct by the end of the Pleistocene, although the exact age of that event was not known until the 1950s when radiocarbon dating placed it at around 10,000 years ago.

Folsom points were lanceolate in shape, very finely made, and distinctive in having a long flake removed from each face running from the base nearly to the tip, giving them a “fluted” appearance. Folsom points immediately set the standard against which all future finds of early points would be compared. As archaeologists searched for additional evidence of early human occupation, they found points that were obviously the same as Folsom points as well as points that were larger, were less finely made, and had shorter flutes. Names for these latter points included generalized Folsom, Folsom-like, and Folsomoid.

During the mid-1930s, Edgar B. Howard and John L. Cotter of the University of Pennsylvania and the Academy of Sciences of Philadelphia conducted excavations at the site of an ancient spring-fed pond on the edge of Blackwater Draw near Clovis, New Mexico, where they found Folsom-like points and beveled bone artifacts associated with remains of mammoths and other extinct mammals.

At the Clovis site, they also found Folsom points with bones of *B. antiquus* stratigraphically above the Folsom-like points. In 1941, the Folsom-like points were named Clovis fluted points. Acceptance of the temporal relationship between Clovis and Folsom points demonstrated here did not occur until Sellards’s definition of the Llano complex.

In 1937, Sellards, as director of the Bureau of Economic Geology and later also the Texas Memorial Museum (both part of the University of Texas at Austin), began two decades of excavations at early paleontological and archaeological sites on the Llano Estacado. Sellards was assisted in his work by the geologist Glen Evans and the vertebrate paleontologist Grayson Meade. This team was one of the first to combine geology and paleontology with archaeology in research on North American human antiquity and to use the geological principles of stratigraphy and superposition.

Two of the sites that Sellards investigated became the basis for his Llano complex. In 1937, Sellards and his team excavated at Miami, Texas, where they found the remains of five mammoths with three Clovis points and a stone scraper. In work at the Clovis site in 1949 and 1950, Sellards excavated a Clovis point, a

bone tool, a hammerstone, and a stone scraper with remains of four mammoths as well as remains of horse, bison, turtle, and small mammals. Sellards excavated Folsom points associated with bison bones in an overlying stratum and demonstrated that the two strata were separated by an erosional unconformity. He emphasized the relationship of Clovis points with mammoth remains and of Folsom points with bison remains. In addition to Miami and Clovis, Sellards included four mammoth–Clovis point sites excavated by other investigators in his definition of the Llano complex: McLean in Texas, Dent in Colorado, Angus in Nebraska, and Naco in Arizona.

By 1952, the Lubbock Lake Folsom site had been dated to approximately 9,900 radiocarbon years before present (rcybp). There were no dates for the Llano complex, but the stratigraphic positions of the two at the Clovis site necessitated that the Llano complex was at least that old. We now know that the Llano complex at Clovis has been dated to 11,300 rcybp and that the Llano complex at Dent had been dated to 10,980 rcybp. Calibrated radiocarbon ages for the same two sites are 13,350 and 12,950 years before present, respectively.

Different people used the concept of Llano culture in different ways. Sellards included all Clovis point sites in his Llano culture, and most followed his lead. Others, however, restricted the name to only sites with both Clovis points and mammoth remains. Still others restricted it to the Llano Estacado and vicinity.

From Sellards’s publication in 1952, the term “Llano culture” competed with the term “Clovis culture.” The former term was used primarily during the 1950s and 1960s until it was largely supplanted by the latter term. “Llano culture” is used only rarely now and is discussed primarily in historic treatments of Paleoindian studies. But Sellards’s demonstration of an older age and association with mammoths for Clovis points and a younger age and association with bison for Folsom points remains unchanged today.

LORENZ, KONRAD (1903–1989)

Konrad Lorenz was a founder of ethology, the biological study of animal behavior. Ethologists study animals in natural and seminatural conditions rather than in the laboratory. They assume that natural selection is largely responsible for species-specific behavior and that the ecology to which the animals have adapted is essential for normal behavior. Lorenz won the 1973 Nobel Prize in Physiology or Medicine for this pioneering work. He shared the award with fellow Austrian Karl von Frisch and one-time Dutch collaborator Niko Tinbergen.

Lorenz grew up in Altenberg near Vienna, Austria, and was a born naturalist. He possessed a unique combination of patience, keen powers of observation, and intuition that allowed him to appreciate the world as his animals experienced it. He kept hundreds of pets. Even before he could read, Lorenz discovered imprinting in ducks, a phenomenon reported incidentally by others at least as early as the 1500s but only first studied in detail by Lorenz.

Lorenz earned his M.D. in 1928 and his Ph.D. in 1933, both at the University of Vienna. Much of his early work centered on a highly social corvid, the jackdaw. He kept a flock in his barn, and in studying them he discovered social imprinting as well as the innate cues used by these birds to respond to food, danger, and each other. His work on jackdaws and other animals is described in his deservedly famous and entertaining book *King Solomon's Ring*.

In 1937, Lorenz and Tinbergen brought their two highly distinctive styles together for a series of experiments on geese that revolutionized our understanding of behavior. In studying an apparently simple response by which geese roll eggs back into their nests, Lorenz and Tinbergen were able to show that there are innate cues (sign stimuli) that trigger the behavior when motivation (drive or what Lorenz called “action-specific energy”) is high enough. The resulting behavior is a fixed-action pattern (often called a motor program), a highly coordinated series of muscle movements that proceeds even if the sign stimuli are removed after it is initiated.

Together with imprinting and other innately directed learning, Lorenz and Tinbergen discovered all of the basic units of innate behavior that guide animals in the wild. After World War II brought their work to a stop for nearly a decade, Tinbergen continued with empirical studies that worked out the detailed nature of sign stimuli, motor programs, drive, and innate learning. Lorenz, on the other hand, began to focus on broader theoretical issues and the relevance of ethology to humans.

In one of his most famous books, *On Aggression*, Lorenz argued by analogy with animals that human aggression is designed for a particular group size and involves a set of rituals designed to create and maintain a dominance hierarchy with a minimum of physical conflict. He argued that as human societies grew from the small communities of hunter/gatherers into towns and cities, innate mechanisms were no longer well suited to the challenge. Group loyalty and territoriality, scaled up to a national level, creates the potential for devastating wars. The anonymity of cities makes high crime levels and pointless violence the norm. He even argued that organized sport is an attempt to satisfy our innate urges for small-scale aggression. Anyone dispassionately watching enthusiastic fans at a game cheering on people they have never met must wonder at the underlying urges.

The provocative writings of Lorenz inspired many others to try to find evolutionary lessons in human behavior, both normal and deviant. He began what decades later would become the field of evolutionary psychology, and his impact on at least popular anthropology was reflected in Desmond Morris's *The Naked Ape*, Robert Ardrey's *The Territorial Imperative*, and scores of other books.

LORISES

Four genera of lorises have traditionally been identified: *Perodicticus* (potto) and *Arctocebus* (angwantibo) of sub-Saharan Africa, *Loris* (slender loris) of Sri Lanka (and possibly also India), and *Nycticebus* (slow loris) of southeastern mainland Asia as well as Borneo and Sumatra. Again traditionally, taxonomists have generally recognized only two species of *Nycticebus* (*N. coucang* and *N. pygmaeus*) while maintaining that the other genera are monotypic. Preliminary morphological and metric studies of skulls and teeth as well as analysis of comparative pelage patterning suggest, however, that what has been attributed to intraspecific variation in both *Perodicticus* and *N. coucang* is best interpreted as reflecting taxic diversity.

Although lorises differ in robustness (pottos and slow lorises) versus gracility (angwantibos and slender lorises), they all are solitary nocturnal insectivores that

are capable of both running quickly and moving extremely slowly and cautiously through vegetation without attracting notice. The latter locomotory behavior is reflected at least in *Perodicticus* having extensive collateral vascularization of limbs, a configuration that appears to be correlated with elimination of lactic acid that would otherwise accumulate during sustained periods of physical activity. In the wild, where *Perodicticus* is sympatric with bushbabies, the potto's diet consists primarily of slow-crawling, noxious insects; in captivity, it selects the bushbabies' typical prey of faster, more palatable insects.

Lorises are prosimian by virtue of their possession of a grooming claw on the second pedal digit and a toothcomb. As a group within Prosimii, lorises are distinguished, for instance, by having noticeably short tails, reduced second manual digits, stubby tubes that grow laterally from the petrosal auditory bulla, and ovoid lower premolars. The relationships among the lorises are still in flux. Although some molecular data have been interpreted as uniting the African and Asian taxa as respective sister taxa, morphology overwhelmingly unites *Perodicticus* and *Nycticebus* (for example, more greatly reduced second manual digits, more rounded gonial regions and deeper mandibles, stouter toothcomb teeth, puffer cusped upper and lower molars, laterally bulging snouts), and *Arctocebus* and *Loris* (for example, thin and elongate long bones, deeper lower molar hypoflexid notches, more pronounced and connected upper and lower molar crests, tubular snouts), as respective sister taxa.

Recently, a new genus and species of a loris relative, *Pseudopotto martini*, was described from material from the Cameroons and was interpreted as the sister

taxon of the traditional loris group, being more primitive than the others, for example, in having a much longer tail, more slender ilia of the os coxa, shorter cervical vertebral spines, and an entepicondylar foramen on the distal humerus. It is craniodentally and skeletally different from, as well as much smaller than, the sympatric *Perodicticus batesi*. To date, *P. martini* has not been definitively sighted in the wild.

The status of *P. martini* is complicated by the fact that the type specimen of *Perodicticus* captured in the Cameroons and identified as “Bosman’s potto” (*P. potto*), which was housed in the Muséum National d’Histoire Naturelle in Paris, is now lost. If it turns out that *P. martini* is a junior synonym of *P. potto*, it might be simpler to petition the International Code of Zoological Nomenclature to retain *P. martini* and designate a specimen of another species of *Perodicticus* as the type of that taxon.

LOVEJOY, C. OWEN

Most of us, at one time in our lives, have probably wondered how we came about and what our ancestral background has been in terms of human evolution. It is an interesting inquiry and one that has received considerable attention by a number of prominent scholars. However, thanks to the efforts of C. Owen Lovejoy, we are coming closer to a better understanding of where we were and where we have come from since the beginnings of the human species. Lovejoy has given us some valuable insights and will probably continue to do so in the future because he is an individual with a solid background concerning past ancestral human origin studies.

Lovejoy has been alluded to as one of the best scholars regarding human evolution. Considering his background and accomplishments, it is easy to understand why he has become the recipient of this honor and reputation. After graduating from the University of Massachusetts in 1968, he began an illustrious career at Kent State University and has continued to make contributions in his profession. He has engaged in fieldwork on numerous occasions but also shares his knowledge with others in a classroom setting. Like many scholars, he has focused on a particular activity within his profession, and that is a strong interest in bipedal locomotion and its changes over time. Although the subjects of his study are obviously quite old, Lovejoy recognizes that there is a connection between the past and the present in terms of what we can learn about ourselves today.

As one would expect, an individual who has engaged in study for a long period of time, and who is also associated with a prestigious university, will likely be one who shares his knowledge with others. Hence, it is easy to understand why Lovejoy’s publication record is outstanding and why it certainly attests to his knowledge about the subject matter that has earned him such a distinction in his professional career.

However, as a complement to Lovejoy’s research interests and academic activities, he has engaged in a number of other pursuits relating to his profession. For example, he has been involved in forensic activities that have been important to public agencies that deal with the criminal justice system. In addition, he has been awarded the prestigious directorship of the Matthew Ferrini Institute for Evolutionary Research, a valuable scholarly entity at Kent State University that will likely bring about new and valuable studies of our human origin. Lovejoy believes in the value of the interdisciplinary approach to his studies, and it should provide him and us with a new and better understanding of our past in terms of human evolution. The Ferrini Institute under his direction and guidance no doubt will also affect future scholars who also have a quest for knowledge concerning human evolution. Considering the fact that the institute is led by a person of renowned accomplishments in his area of specialty, this will no doubt come about soon and contribute substantially to a better understanding of that part of our ancestral past that is of so much interest to, or holds so much intrigue for, many of us.

LUCRETIUS (94/95–51/55 BCE)

Very little is known about the author Lucretius, whose full name was Titus Lucretius Carus. *De Rerum Natura* (*DRN*) [On the Nature of Things] likely was his only work. Later Christian authors, hostile to Lucretius's views on religion and his statements about the death of the soul, invented some fantastic stories about him, according to which he composed his work *DRN* in a delirium, poisoned by a love potion administered by his wife. Driven to distraction, he committed suicide. Modern authors discard these stories as untruths.

Lucretius lived during turbulent times. Caesar was engaged in his conquest of Gaul, and the Roman army was slowly turning into an army of mercenaries more loyal to generals than to the Roman people. The Social Wars had greatly weakened popular representation, and the people of Rome had lost all power or say in their own government. Soon, civil war would break out and emperors would rule Rome as conquests, confiscations, slave revolts, crucifixions, political conspiracies, and murders increased in number. Lucretius favored a withdrawal from public life and preferred quiet observation. In his scheme, it is the fear of death and of the gods that leads individuals to desire wealth and power beyond what is required for a peaceful and happy life.

Work and Philosophy

Lucretius gave himself the difficult task of expounding the ideas of the Greek philosopher Epicurus (341–270 BCE) in the form of a didactic poem in Latin hexameters, “On the Nature of Things.” Epicurus’s influence is felt throughout *DRN*. Most of this author’s works

are lost, but his arguments outlined in his *DRN* have survived in the writings of others. Epicurus and his followers argued that humans should have one goal in life: happiness (i.e., absence of fear and want). Knowledge of the physical world and a theory of knowledge (epistemology, i.e., how we know what we know) were aids to achieving happiness. The Epicurean philosophers believed that all life on the earth was made up of matter, with atoms (“things which cannot be split”) being the smallest constituents. Thus, anything that happens in the world has a natural cause that can be revealed by a thorough investigation.

As is customary in didactic poetry, the author addresses a friend (Memmius) and, through the friend, addresses the reader. The poem is divided into six parts, or books, and its total length is 7,415 lines. During Roman times, philosophy included what we would now call “science”—the knowledge of natural phenomena, the gods, life, death, religion, human societies, animals, the stars, inanimate matter, and so on. Lucretius (and his contemporary Cicero) refashioned the Latin language to accommodate the abstract concepts developed by the Greek philosophers of nature. For Lucretius, poetry was the medium of choice: there was a centuries-old tradition of didactic poetry at his time, both Greek and Latin. Moreover, poetry appeals to the senses and thus conveys abstract concepts more easily. As Lucretius phrased it, a poet is like a doctor who smears honey around the rim of the cup that so a child will take his bitter medication.

The poem begins with an allegorical invocation of the goddess Venus, the goddess of love, the beginnings of life, and the mother of the founding father of Rome, Aeneas. It ends with a vivid description of the Plague of Athens taken from Thucydides’s *The Peloponnesian War*. Life is a cycle of birth and destruction, of rise and fall. A true understanding of Epicurus teaches us to accept such cycles and to not add to our agony by fear of an afterlife.

In Books II and V, Lucretius argued that the world came into existence by itself—the happy joining of the right atoms at the right time—and that slowly the primeval mud brought forth first grasses and then smaller animals, birds, larger animals, and finally humans. But the earth, the skies, the stars, the sun, the moon, and the oceans all are made of perishable materials and will also die one day. The earth gave birth to everything, but it also represents a shared grave.

Space is infinite, and particles move in all directions; therefore, it is very likely that combinations of atoms like the earth, including humans and animals, also occur elsewhere.

Lucretius's materialistic approach to the world denied the influence of the gods on human life; the gods exist, but because their goal (happiness) is similar to that of humans, they do not need human prayer and sacrifices. The gods also did not have anything to do with the creation of the world. The gods live forever, but the human soul dies when the body dies; thus, fear of the gods (for example, punishment for sins) is useless. Fear of death is useless too because all sensation stops at death. Lucretius's argument that human reason could explain the universe without having recourse to divine intervention was suppressed for nearly 1,700 years until the philosophers of the Enlightenment came to the same conclusion: "Little by little time teases out all discovery, and Reason (Ratio) brings it out into the regions of light." Lucretius's poem played no small role in this revival, although authors of the Enlightenment were conflicted about his ethics and views on religion as opposed to his views on science and progress. Important authors include Gassendi, Montaigne, Dryden, the Cardinal de Polignac ("Anti-Lucretius: Or, on God and Nature" a poem in which he attacked Gassendi, Hobbes, Newton, and Locke), Helvétius, Holbach, Diderot, and Voltaire ("Letter of Memmius to Cicero"), among many others.

Inherent in Lucretius's (and the other Epicureans') understanding of the world as a material construct is his explanation of human societies introduced at the end of Book V. This part of *DRN* has often been mentioned as one of the first manifestations of evolutionary thought and is thus highlighted in many works that tell the story of anthropology's first beginnings, even though it is discussed in only 700 verses. Lucretius's explanation of the stepwise development of human societies follows logically from his main point that everything has a natural cause. Lucretius pointed out that we have no empirical evidence of the world's first beginnings, but analogy (and metaphor) can provide us with a fair idea. At first, humans lived like animals—sleeping by night, hunting by day. Just as animals have different cries for different emotions, so did humans, and eventually these sounds developed into a shared language. Life was short and violent; on the other hand, humans did not die in foolish wars or drown at sea in pursuit of wealth.

Sometimes they starved and died; today, humans die of overeating. Every so often, humans poisoned themselves by accidentally eating the wrong thing; today, they actively poison each other. Gradually, humans learned to live in huts, to make fires, to be kind to each other, to be monogamous, and to care for their children because it is right to care for the weak. Next came kings and the parceling out of land, followed by "the invention of property and the discovery of gold." Today, the rich rule rather than the deserving or the beautiful; those in charge now violate "the mutual compact of social life," a concept taken nearly verbatim from Epicurus. Throughout his *DRN*, Lucretius condemned greed, politics, and romantic love, all evidence of human folly and irrationality. In Book V, the poet came very close to satire when he showed that material and technological progress and comfort have not made humans any happier. Early life on the earth, although crude, was used as a foil for modern corruption.

Epicurus's recipe for human happiness was reviled by later Christian authors, especially because of his attacks on *religio* and mortality of the soul. It was mainly the doing of later authors that gave "Epicurean" its current meaning of a hedonistic approach to life. The original doctrine recommended moderation or nearly asceticism; a glass of water served to slake thirst as well as the most expensive wine.

LUCY RECONSTRUCTION MODELS

Lucy is among the most famous fossil skeletons believed to represent an early stage of hominid evolution following separation of the human lineage from

its nearest living ape relative. At 3.2 million years, Lucy was the oldest and most complete hominid skeleton that clearly showed evidence of bipedal locomotion. The label “Lucy” provided a personal metaphor for an individual believed to be a female approximately 20 years of age at the time of her death. Classified as *Australopithecus afarensis*, Lucy was one of nine species clustered under the genus *Australopithecus* despite a poor understanding of their evolutionary relationships and status.

Numerous portraits of the australopiths have combined the constraints of fossil morphology with the addition of soft tissue features that are imagined to be present based on the presumption that Lucy and other early hominids resembled those apes most closely related to humans. Because those apes are widely believed to be chimpanzees, based on the similarity of DNA base sequences between chimpanzees and humans, the soft tissues assigned to Lucy are those of chimpanzees. Lucy and other early hominids are given the fleshy nostrils unique to chimpanzees and gorillas among the living primates. The body hair is short and dark and projects away from the face as with chimpanzees, and there are no beard and mustache present in males because it is not found in chimpanzees. Instead, sparse hair is shown on the underside of the lower jaw, whereas the forehead is imagined to be free of hair as with humans but unlike chimpanzees.

Although the soft tissues may be a matter of conjecture, the hard tissues offer some constraints that are problematic for any chimpanzee reconstruction for Lucy and other australopiths. The forward-projecting brow ridge extending across and between the eyes that gives chimpanzees and gorillas that classic hooded appearance is missing. Instead, the ridges of Lucy and other australopiths are limited to the region immediately above the eye. Neither do the eyebrow ridges project forward in the manner of chimpanzees and gorillas. Also absent is the channel or sulcus that lies immediately behind the brow ridges in chimpanzees and gorillas. In addition to the absence of these African ape features is the presence of a different kind of cheekbone. The cheekbone of the chimpanzee is narrow and slopes back along the lower margin. The complete opposite is found in australopiths, where the cheekbone is very broad and is vertical or slopes forward at the lower margin.

The combination of these three features is hardly congruent with what might be expected of a chimpanzee ancestry for humans. When artists add

chimpanzee features in their reconstructions of australopiths, the result is a very incongruous bipedal “chimpanzee” that has massively broad cheekbones and lacks the classic supraorbital ridge (torus) and posttoral depression of African apes. Perhaps their absence may be attributed to an evolutionary loss of the features since separation from the common ancestor with chimpanzees, whereas the cheekbones are just a novel development that was then later lost in the evolution of *Homo*. This ad hoc scenario may be all well and good, but there is another great ape that shows no such contradictions in skull structure.

Comparisons between australopiths and orangutans demonstrate no such obvious contradictions of skull morphology. Orangutans have broad cheekbones with forwardly oriented lower margins as with Lucy and other australopiths. Orangutans also have eyebrow ridges that do not project up in the African ape manner. These similarities may be passed off as a

Lateral view of *Australopithecus africanus* specimen Sts 71 from Sterkfontein. This view illustrates the lower surface of a flattened orbital plane and anterior orientation of the zygomatic roots.

phylogenetically meaningless coincidence, but there are at least 42 known features uniquely shared between orangutans and humans—far more than any uniquely shared features between humans and chimpanzees. The skull of the australopiths also shows several skeletal features that are otherwise characteristic of orangutans or recognized orangutan relatives, including upper palate thickness, nasal bone thickness, and cheekbone development.

The orangutan resemblance of australopith Sts 71 is further emphasized by a more forwardly projecting upper jaw and a more marked disparity in size and shape between the upper central and lateral incisors. Although the skull of Lucy is represented by only a few fragments, these are shown in reconstructions to be part of a skull that has an overall similarity to that of the chimpanzee with a relatively low domed cranium on the assumption that the early hominids would show chimpanzee-like skeletal features. This assumption was recently found to be wanting in a reconstruction of *A. afarensis* using a more complete

skull for this species. By carefully connecting the skull fragments of the fossil AL 444-2, William Kimbel and colleagues recently developed a most un-chimpanzee-like reconstruction. In addition to the orangutan-like brows and cheekbones, the infraorbital region of the lower region of the face is flat and vertical rather than concave as with chimpanzees. Even the upper jaw shows a slight upward inclination, and the cranial area rises in a gradual dome as with orangutans.

Collectively, the structural features of Lucy and other australopiths give an appearance that is more like orangutans than chimpanzees. When these features are combined with soft tissue features that would be expected of an African orangutan relative, a completely new interpretative portrait becomes possible. This potential was recently explored by the scientific illustrator Bill Parsons at the Buffalo Museum of Science. The result shows a new kind of “Lucy” with the flat, vertical infraorbital region and high cheekbones indicated by skull morphology. In addition, the hair is now forwardly oriented, the forehead is exposed, the nostrils lack the fleshy extensions found in

African apes, and Lucy can smile without showing teeth. All of these features are uniquely shared by humans and orangutans, and if these and other unique features indicate a common ancestry, then they can be fully expected to have occurred in early hominids such as Lucy.

The new portrait of Lucy is now on display at the Buffalo Museum of Science in the world’s first exhibition showing the contrasting chimpanzee and orangutan reconstructions of early hominids. The purpose of this display is to show that it is possible to derive different results by emphasizing different elements of the same information. The orangutan connection with humans is generally ignored in favor of the chimpanzee connection principally through the widely accepted view that genetic base pair sequence similarities between humans and chimpanzees are the final and only proof of hominid evolutionary relationships. The trouble with this proposition is the fact that australopiths do not look like chimpanzees. Instead, the clearly orangutan features of Lucy and her relatives

Bust of Lucy interpreted from a recently reconstructed skull of *Australopithecus afarensis* supporting a cranial profile with a flattened and vertically inclined orbital region, broad cheekbones, and absence of the African ape supraorbital torus. This illustration, by the scientific illustrator William Parsons, is currently on display at the Buffalo Museum of Science.

suggest something quite different—different enough to make one smile just like an orangutan.

LYELL, CHARLES (1797–1875)

Charles Lyell was born in Kinnordy, Forfarshire, Scotland, on November 14, 1797, the eldest of

10 children. His father guided his early studies of nature, but Lyell's formal education was received at Exeter College of Oxford University. While there, Lyell was influenced by the works of William Buckland, a geologist and paleontologist. After graduating in 1816, Lyell studied law, but by 1827 he had abandoned the profession to start a long, full-time career in geology. His writings would enhance the ideas proposed by James Hutton, a Scottish geologist considered by many to be the father of modern geology and noted for formulating the concepts of uniformitarianism, in his *Theory of the Earth* (1795) as well as the Plutonists' school of thought. Hutton's new theory was based on his observations that layers of sedimentary rocks, thrust up against other layers at various angles, pointed to the fact that layers had been deposited, transformed into rock, and then tilted only to have further deposition on top. He also proposed that the interior of the earth was hot and that the movement in this "heat engine" resulted in the formation of new rock. The presumption was that these tremendous displacements of rock happened gradually, requiring a vast amount of time to slowly produce the various topographies. A corollary to his argument was that the same geological processes at work today were in operation in the past, whereas the prevalent notion at the time was catastrophism, which stated that all rocks had precipitated out of an enormous flood in a very short time span. Hutton's view of the geology of the earth had "no vestige of a beginning, no prospect of an end."

Lyell was also committed to this steady-state, nondirectional, and nonprogressive view of uniformitarianism. Changes were gradual and continuous, but with no direction. He rejected Hutton's thesis that the earth had been molten when it was first formed and that it was in the process of cooling. This denial posed a serious impediment by ignoring the relevance of astronomy and physics to historical geology.

From 1830 to 1833, Lyell published his three-volume *Principles of Geology*. The work's subtitle was *An Attempt to Explain the Former Changes of the Earth's Surface by Reference to Causes Now in Operation*. However, it restricted all geological explanations to causes that can be observed in the present, ruling out any catastrophies because they are non-observable in the present, and therefore rejecting them as past events to explain the present formations.

Source: Courtesy of the Library of Congress.

Lyell believed in the uniformity of the laws of nature, as did the catastrophists. His position may be summarized by pointing out not only that geology was to restrict its hypotheses to the same kind of causes as those currently acting but also that the intensity of those causes is to be in the same range that currently exerts itself. This view of uniformitarianism rules out the possibility of a developmental theory of the earth.

Lyell's *Principles of Geology*, and its many revisions, was the most influential geological work of its day and did much to lay the groundwork for the fledgling science of historical geology.

Another important area of geological endeavor was in the field of stratigraphy, a branch of geology concerned with the relationship between sedimentary rocks and their depositional environment. As a result of his fieldwork in Italy and France, Lyell was able to categorize recent strata by kind and proportion of fossil marine organisms, resulting in his proposed division of the Tertiary Period into three

segments that he named the Pliocene, Miocene, and Eocene. The second edition of his *Principles of Geology* explained new ideas concerning metamorphic rocks. It delineated the rock changes due to high temperatures in sedimentary rocks adjacent to igneous rocks.

The impact of Lyell's geological uniformitarianism on Charles Darwin was significant and had staggering results. Darwin read the *Principles of Geology* during his 5-year voyage on the HMS *Beagle*. It provided Darwin with the background to contemplate those formations that could result in geology by small and slow processes operating over immense periods of time. Darwin's early papers were, in fact, attempts to explain geological and biological features (i.e., his coral reef work) in a uniformitarianistic manner. His later *On the Origin of Species* (1859) relied on these same premises.

Although Lyell inspired Darwin and became his lifelong friend and mentor, his approach in applying the principles of uniformitarianism in a steady-state, nondirectional, nonprogressive world to the history of living organisms put him in initial disagreement with Darwin the evolutionist. Lyell maintained that the fossil record had no development from simple organisms to more complex ones because the earth always has sustained the full range of living organisms, even predicting that the fossils of mammals could be found in the oldest sedimentary rocks. He believed in the fixity of species, although he acknowledged that many new species had become extinct and that all ecological niches were always occupied with many new species coming into existence, but not something observable in the present. He refused to specify how or what he meant, leaving the interpretation open to discussion.

Later in his life, Lyell acknowledged the accumulation of evidence regarding the evolution of organisms over time and became one of the first prominent scientists to endorse *On the Origin of Species*, although he never fully accepted natural selection as a driving mechanism behind evolution in his public writings. In 1858, Lyell was in fact instrumental in arranging the copublication of the theory of natural selection by Darwin and Alfred Russel Wallace. Darwin had withheld publication of his accumulated evidence regarding natural selection for more than two decades. He was forced into publication due to the independent discovery of a similar

theory by Wallace, who sent Darwin his paper titled “On the Tendency of Varieties to Depart Originality from the Original Type.” In 1863, Lyell published his *Geological Evidences as to the Antiquity of Man*, discussing Darwin’s theory at length.

For his contributions to the science of geology, Lyell was knighted in 1848 and was made a baronet in 1864. He died on February 22, 1875, and is entombed in Westminster Abbey, as is Charles Darwin.

The Maasai live in rangelands in Kenya and Tanzania. Accurate census data are not available, but estimates of population numbers range between 500,000 and 1,000,000. The Maasai speak a Nilotic language, and their social system is structured by sections (which control areas of space), clans (which run across the whole land), and age-sets (bands of men of similar ages).

The Maasai are probably one of the most famous groups in Africa, and certainly in East Africa, due to their persistent preference for bright beads and blue and red clothes over modern dress and their predilection for cattle. They are popularly believed to value cattle as wealth regardless of the utility of cattle, and they subsist on a diet of milk and blood. They are also famous due to the concentrations of wildlife with which they have shared their land and the beautiful landscapes (e.g., at Ngorongoro, near Kilimanjaro) with which they share them.

The large herds of the Maasai reflect the logic of subsistence milk production and herd survival in arid environments as well as concerns for prestige. But despite the prominence of livestock, Maasai and Maa speakers have long adopted a variety of livelihoods, including agriculture and hunting. Maa speakers have farmed and hunted when raids, drought, or disease reduced cattle numbers. Even during times of plenty, trade of livestock products for grains has been the norm. A purely pastoral diet was a luxury enjoyed by herders in remote cattle camps during the wet season. It may even have been an unusual, and brief, historical development in the long history of pastoralism.

One of the clearest current trends in Maasai society is the decline in livestock per capita. Cattle numbers are fluctuating around a set number, whereas human populations are increasing. As a result, fewer and fewer Maasai are able to live off their herds, and diversification into agriculture, tourism, and diverse businesses is the norm.

Nevertheless, despite the commonplaceness of diversity, the ideological ground of pure pastoralism has remained strong. Who precisely is *really* Maasai is a question that has dominated the Maasai and their governments for many years. The Maasai are contemptuous of “non-Maasai” (*Il-Mek*, i.e., “bumpkins”) and believe that they have a right to repossess their cattle, which God gave to the Maasai. Colonial governments in particular, because they sought to make ethnic boundaries and territory rigid, also had tremendous difficulties in deciding who was and was not really Maasai. The reality is that ethnic identity, like livelihoods, is fluid and dynamic. Belonging and identity could and can shift. It was because of this dynamism that debates about identity were so intense.

Maasai recent history has been dominated by land. In the Maasai moves of 1904 and 1911, the British government evicted the Maasai from their lands in the middle of Kenya and concentrated them in a single Southern Reserve, breaking a promise that had allocated them land in the north. Since then, herders have also been moved from private farms and wildlife reserves, including the famous Amboseli and Serengeti national parks and the crater inside Ngorongoro.

Current burning issues in Kenya and Tanzania revolve around land titling and subdivision that threaten the free movement of herds. There is also

continuing conflict with the wildlife lobby, which is seeking to preserve wildlife's access to pasture and water through both cooperative and coercive measures. Recent scholarship has also emphasized the constructions of patriarchy and gender in Maasai society through encounters with patriarchal governments.

MACAQUES

The macaques are successful Old World monkeys (family Cercopithecidae) that are members of the genus *Macaca*, of which there are some 20 species. Macaques are the most wide-ranging primate species except for humans. One species, *M. sylvanus* or the Barbary macaque, is found in Morocco, Algeria, and Gibraltar. The other species are found from Afghanistan to Beijing and from Sri Lanka through Indonesia to Japan. *M. mulatta*, or the rhesus macaque, has the widest distribution and is found from eastern Afghanistan through northern India to southern Vietnam and southern China. Other macaques have a more limited distribution, including those of Sulawesi and Indonesia and *M. silenus* (the lion-tailed macaque), which is found only in the Western Ghats of India.

Macaques are small to medium-sized monkeys, most of which have a brown or grayish pelage, although a few macaques such as *M. nigra* have black hair. They have naked faces and ears, and their tails vary in length from nearly no tail (e.g., *M. arctoides*)

to tails that are the length of the body or longer (e.g., *M. fascicularis*). Macaques are quadrupedal and basically arboreal, although some species such as *M. mulatta* spend more than half of their time on the ground. Other traits of macaques include cheek pouches and ischial callosities or sitting pads. Their diet is composed mainly of vegetation (fruit, leaves, flowers, and bark) and insects and other invertebrates.

The fossil record of the Old World monkeys is known from the early and middle Miocene, with a group of remains recognized as belonging to two African genera: *Victoriapithecus* and *Prohylobates*. These two genera preceded the separation of the two extant subfamilies of Old World monkeys: Colobinae and Cercopithecinae. The Old World monkeys shared a common ancestor with the hominoids (i.e., the apes), diverging during the late Oligocene or early Miocene. Overall, monkey fossils from the Miocene are rather scarce compared with the numerous fossil hominoids. Macaques appear in the fossil record during the late Miocene and early Pliocene, first in Africa and subsequently in Europe and Asia. Today only 1 macaque species still inhabits North Africa (*M. sylvanus*), 19 species live in Asia, and none is found in Europe. After 5 million years of successful evolution, many species of macaques are facing extinction due to human activities. According to the International Union for Conservation of Nature and Natural Resources, 57% of macaque species are either endangered or vulnerable, and if one adds the near threatened and conservation-dependent species, the number increases to nearly 100% of the macaques potentially facing extinction. Human greed, overpopulation, and lack of compassion are the reasons why the number of macaques is declining worldwide.

The basic macaque social system is called the multimale, multifemale troop in which females remain in their natal troop and males move to a non-natal troop or become solitary. The core of the multimale, multifemale troop is the matrifocal units composed of related females. Males and females have dominance

hierarchies, but males (being larger than females and possessing larger canine teeth) are dominant to females. Rank among females is often inherited from their mothers. There is, however, some variation in this basic social system. For example, in rhesus and Japanese macaques, the males are consistently forced out of their natal troops when they reach sexual maturity around 5 years of age, but bonnet macaque males have been known to remain in their natal troops. The dominance hierarchy is generally stronger in those troops fed by humans than in those that survive by foraging on natural vegetation.

Males and females become sexually mature between 4 and 7 years of age. In the wild, macaques rarely live past 20 years of age. With an interbirth interval of 1 to 2 years, a healthy female can expect to produce 5 to 10 offspring over the course of her lifetime and to live long enough to become a grandmother. Sexual behavior is promiscuous, and females mate with both troop and nontroop males. Mating may be observed throughout the monthly menstrual cycle and during the early stages of pregnancy. In addition to heterosexual behavior, masturbation and homosexual behavior have been reported for several species of macaques.

Macaque communication is multimodal in that macaques communicate with facial expressions and body postures, vocalizations, odors, and touching such as grooming and huddling. Macaque communication usually involves dominance, submission, aggression, and reconciliation; mother–infant relationships;

warnings of danger; friendly overtures; and messages before, during, and after sexual encounters.

Two epic legends and other myths influence the interaction between people and macaques. The Hindu *Ramayana* is one such legend in which a monkey god-servant of Lord Rama named Hanuman plays an important heroic role. The other legend is a Chinese epic called *Journey to the West* in which the Monkey King or Sun WuKong (in Mandarin) is a central character. There are also numerous myths whereby Buddha is reincarnated as a monkey and performs heroic acts. In Asia, there are many variations on these myths and differences in the depictions of the monkeys in the myths. The end result is that macaques are often tolerated and provided with food around temples and other sacred places. Moreover, macaques are often dependent on humans for food because much of their natural habitat has been destroyed. The future of macaques in Asia depends on the good will of the people of Asia and their willingness to provide for their wildlife.

Although the *Macaca* genus as a whole is monophyletic (i.e., all species share a common ancestor that was also a macaque), some species of macaques seem to be more closely related to each other than to other macaque species. Although a complete consensus has not been reached, the list of genus and species that follows is arranged according to evolutionary relatedness following Groves's *Primate Taxonomy*. The species/groups are based on studies of morphology and genetics. It should be noted, however, that macaques, when given the opportunity, will hybridize and produce fertile offspring.

MACHU PICCHU

The pre-Columbian empire and state system of the Incas of South America created Machu Picchu during the mid-15th century as a royal Incan estate. Machu Picchu, a Quechua Indian term translated as “old or ancient” peak, is located just 50 miles northwest of Cuzco, Peru. It sits on the eastern side of an Andes mountain peak 8,000 feet above sea level overlooking the Urubamba River valley. Farther to the east extends the tropical rain forest. To the west, across more mountainous peaks, lies the Pacific coast. The city size fortress was abandoned shortly after the time of the Inca Empire collapse in 1540 and laid in ruins when Hiram Bingham, a Hawaii-born Yale University professor, rediscovered it in 1911 during his search for the Inca city of Vilcabamba. Bingham’s landscape and architectural photographs supplemented his many field notes, providing hypotheses for field expeditions to follow.

As archaeologists recover the features of Machu Picchu, they debate its complex functions. It is thought

to be the country estate of Inca leader Pachacuti, regarded as the greatest Inca ruler. The roads and pathways that linked Machu Picchu to Cuzco suggest that royalty used it as a retreat from bustling Cuzco nestled in the mountains below. For security, there was only one main entrance to the strategic mountaintop site. On the path to Machu Picchu, the Incas developed a drawbridge made of wooden planks or logs placed over a gap on the narrow orchid-lined footpath. It could be removed for protection from possible invaders.

Machu Picchu is known for its highly complex and sophisticated architecture. Most of the urban structure was constructed of granite hauled great distances with conscripted manual labor using simple levers. The stones were carved to fit so well that it is said that a knife or piece of paper could not pass between the stones at any point. An example of Inca stonework is found in the cylindrical Tower of the Sun that houses the Royal Tomb. The Incas applied their knowledge of gravity, stonecutting, and natural springs to create various stone canals, gutters, and storm drainage systems for water diversion. Their expertise in stonework and hydrology enabled them to create 16 fountains that relied on the groundwater of the mountains to supply the private bathrooms and kitchen of the royal quarters. Excavations reveal bronze weapons and stone tools. Archaeologists say that there are still more mysteries to uncover in Machu Picchu.

Machu Picchu has three main sectors: agricultural, religious, and urban residential. The religious sector features the Intihuatana shrine to the sun god Inti. It is a square structure, with its corners pointing in the four cardinal directions of the earth. Machu Picchu is situated in the midst of significant mountain sites, leading many to speculate on its religious significance. The Temple of the Three Windows, which is trapezoidal in shape, and the Temple of the Condor, in which the Incas carved a stone head in front of two large granite rocks that resembled condor wings, are significant architectural accomplishments. The agricultural sector incorporated the high terraces on the mountain’s edge for planting crops such as potatoes and maize. The urban sector was made up of the main courtyards and grassy areas. Many craftspersons lived and worked there, serving the royal family. Houses were usually arranged in small groups. They were constructed of stone, and roofs were woven with thatch.

The words “magic” and “magical” are used in many different ways to refer to a huge variety of supernatural or wondrous phenomena, and even within

anthropology there is inconsistency. So varied have been referents of the terms that some scholars have insisted that they have no cross-cultural validity and have urged that they not be used at all. But the word *magic* is firmly rooted in our language; it has been important in the development of anthropological theory, and ethnology has enabled the description of a set of features of magic that reveal important capacities of human cognition and cultural conceptualization.

When the word *magic* is encountered, the student should take care to ascertain just what it means. Some of the most common meanings of magic and magical include illusion or sleight-of-hand performed for entertainment; the ability to change something’s form, visibility, or location or to create something from nothing; spirit invocation and command; and having romantic, awe-inspiring, or wondrous qualities. During late medieval and Renaissance times, magical practices involving complex calculations and/or written notations and formulas based in esoteric knowledge were designated as high or hermetic magic to distinguish them from the “low” or simple magic of the uneducated peasantry. Any of the many meanings

of *sorcery* or *witchcraft* may be labeled *magic*; indeed, these three terms are often used interchangeably. Sometimes modifiers, such as “black” (or white) magic and “demonic” magic, are used. During the 19th and early 20th centuries in Europe and America, a number of organizations devoted to “occult” practices developed. Some of these, such as the Ordo Templi Orientalis (Order of the Eastern Temple) and Order of the Golden Dawn, still exist today and designate their specialized ritual practices by the spelling *magick*. During modern times, the terms may designate anything psychic, paranormal, occult, or “New Age” or may designate any of the beliefs and practices of neopagan organizations such as Wicca, whose practitioners also prefer the spelling *magick* or, indeed, any reference to supernatural power or anything seeming miraculous or wondrous. The best anthropological meanings of the terms are quite different from any of the preceding meanings, but it has taken well over a century to arrive at them.

Magic in the History of Anthropology

Influenced by earlier positivism and contemporary evolutionism, scholars of the late 19th and early 20th centuries were interested in magic mainly as it related to religion and science. E. B. Tylor, in his *Primitive Culture* (1871), recognized that magic is based in principles of association, “a faculty which lies at the very foundation of human reason,” but he gave it no serious cognitive significance because the assumption of causal connections among associated things, although examples of it survived into modern times, is so clearly false that it represented a primitive stage in human thinking. James George Frazer built on Tylor’s writings and set down his lasting theory of sympathetic magic in the third edition of his monumental work, *The Golden Bough* (1911–1915). Frazer insisted on the evolutionary progression from magic through religion to science, and he maintained that the roles of magician and priest are separate and opposed, although he acknowledged that the principles of magic might combine with those of religion.

Marcel Mauss and his colleague Henri Hubert, in *A General Theory of Magic* (1902–1903), recognized the practice of magic as individual and private but emphasized its social implications. They focused on the Melanesian and Polynesian concept of *mana* as exemplifying the mystical power at the core of magical beliefs. The discussion of magic by Mauss’s uncle

Émile Durkheim, in his *The Elementary Forms of the Religious Life* (1912 in French, 1915 in English), emphasized its distinction from religion; magic is derived from religion, but it is individualistic and hence has no role in social solidarity and no place in his theory of religion.

The Melanesian investigations of the great British social anthropologist Bronislaw Malinowski produced two works about magic that were influential within and beyond anthropology: his great essay “Magic, Science, and Religion” (1925) and the two-volume *Coral Gardens and Their Magic* (1935). In his functionalist theory of culture, Malinowski emphasized that magic is neither primitive science nor a confusion of thinking but rather is a quite logical complement to practical knowledge and technique, integral with and routine in mundane activities. Malinowski paid special attention to the magic act, which has three components: the formula, the rite, and the condition of the performer. He also elaborated at length on the nature and importance of magical speech.

E. E. Evans-Pritchard was a student of Malinowski, and he also presented magic as a rational system of thought, but his great work *Witchcraft, Oracles, and Magic Among the Azande* (1937) stimulated anthropological investigations of witchcraft. With a few exceptions, social science discussion of magic over the subsequent six decades broke little new ground, presuming its uniqueness as a cognitive category separate from religion, and doubted its utility as a cross-cultural category. In his famous Frazer Lecture on taboo in 1939, Alfred R. Radcliffe-Brown advocated avoidance of the term *magic* until there was uniform agreement about its meaning. The French structuralist Claude Lévi-Strauss, in his introduction to a collection of Mauss’s major works in 1950 (English translation 1987), agreed that the universality of a mana-like concept represents “a permanent and universal form of thought,” but he criticized Mauss for having reduced “all magic” to mana, which is in fact a specific cultural concept and which differs greatly among various Melanesian and Polynesian cultures. And in his foreword to the 1972 English translation of Mauss’s *General Theory*, David Pocock said that “the importance” of the appearance of Mauss’s work at that time, with Lévi-Strauss’s commentary about it, “is that it contributes to the dissolution of ‘magic’ as a category.”

Alice and Irvin Child observed in their *Religion and Magic in the Life of Traditional Peoples* (1993) that “Frazer’s study of primitive magic was getting at

fundamentals of human thought,” but throughout the 20th century most discussions of magic were premised on assumptions of its falsity and cognitive infancy; it was dealt with as of a totally separate order from religious phenomena, and scholarly concerns with various aspects of its mode and expression precluded investigations of its underlying cultural meanings or cognitive significance. Rosalie and Murray Wax provided an overview in their 1963 essay, “The Notion of Magic.” A comprehensive general social science survey, using “magic” to cover a wide range of techniques of supernatural manipulation, was Daniel O’Keefe’s *Stolen Lightning: The Social Theory of Magic* (1983). Stanley J. Tambiah’s *Magic, Science, Religion, and the Scope of Rationality* (1990) contained insightful assessments of major anthropological studies of magic.

Magic in World Ethnology

Michael F. Brown, in his comprehensive ethnography of magic among the Aguaruna of northern Peru, *Tsewa’s Gift* (1986), showed that for these people magic is not distinguished conceptually from religious or instrumental activity, and he seemed to echo Evans-Pritchard’s discussions of 50 years earlier: “nor is its logic independent of prevailing notions of material causality.” Brown urged more careful examination of the underlying symbolism of magical thinking and recognition of the full integration of magic in cultural conceptualization and expression. Anthropology today has the data, methodology, and philosophy to study magic as a basic mode of human thinking.

Ethnology, the cross-cultural comparative method of anthropology, has revealed certain principles that underlie magical thinking and are absolutely universal and for which there is evidence throughout recorded history and even in prehistory. The fact of their universality, strengthened by some recent discoveries in the brain sciences, suggests that we are dealing with fundamental structures of human cognition. Magic is best understood as beliefs and behavior involving at least some of six basic principles: power, natural forces, symbols, cosmic interconnections, and Frazer’s two principles of sympathetic magic (similarity and contact).

Power

Power is the universal idea that Mauss recognized, although it has specific variations and no single cultural concept, such as mana, should be used to

generalize. People everywhere believe in a mystical communicable vital force that exists to varying degrees in all nature. Inanimate things have less power than animate things, lower order animals have less power than higher order beings, power increases in intensity up social and supernatural hierarchies, and contact by lower order beings with higher order power is dangerous. The biblical concept of God’s “glory” is an example. In people, power is carried in the blood and the breath and is energized by thought and intent. It is concentrated in the reproductive organs, and it is embodied in words and semen and menstrual blood and breast milk. Negative, especially dangerous forms of it are emitted through the excretory orifices and bodily lesions.

Natural Forces

All people also seem to believe that all nature is activated by forces that can be conceptualized as the engines of nature. They are energized by their own power and are programmed to do specific things, either singly or in concert with others. The forces can be manipulated by spirits, either of their own accord or after supplication by people through prayer and ritual, and they can be affected directly by people through magic without spiritual assistance.

Ethnology also reveals that the invocation and command of spirits is a universal feature of religion but that it ought to be reconsidered as a feature of magic. Probably all religions regard at least most of their spirits as sentient, willful, and potentially capricious, and all recognize serious risks in attempting to contact spirits directly and especially to command them. Conceptually, there is a great difference between the invocation of and effort to persuade presumably sentient and willful spiritual beings and the effort to exert direct control over presumably nonsentient forces of nature. Frazer, influenced by Tylor’s theory of animism, did recognize this problem, and he tried to get around it by arguing that when magic addresses spirits it treats them as “inanimistic agents” that submit passively to the magician. This lame assumption is unjustified in world ethnology and is surely one of the weakest points in Frazer’s generally insightful theory of magic. Even though apparently magical techniques may be involved, spirit invocation and command should be regarded as a distinct phenomenon of religious behavior and not categorized as magic.

In many systems, forces and power might not appear separate but may seem to merge, as in mana,

Chinese *qi*, Greek *dynamis*, and the various concepts of flowing energies in traditional and New Age belief systems.

Symbols

Symbols are central to magic. Symbols are forms of representation that not only stand for other things but also can conceptually take on qualities of those other things so that they *stand in for* or take the place of those other things. If the thing the symbol represents has power, the symbol will become powerful. Words are symbols; so too are thoughts. Representations of religious beings and concepts and reproductive organs are especially powerful symbols. The power of symbols, containing the essence of the thing or act symbolized, can be projected through magic.

Cosmic Interconnections

People everywhere believe that all things in nature—past, present, and future—are mystically interconnected, either actually or potentially. And it is widely believed that everything that has happened, is happening somewhere else, or will happen is cosmically programmed and detectable. Magic can project influence through these connections.

Frazer's Principles of Similarity and Contact

In his discussion of sympathetic magic, Frazer provided the best explanations for how the magical symbol is believed to work. Influenced by theories of positivism and natural law, he said that sympathetic magic operates according to the “law of sympathy,” which has two subtypes: the “law of similarity,” which states that things or actions that resemble others have a causal connection, and the “law of contact,” which states that things or actions that have been in contact with others, either spatially or temporally, retain a connection after they are separated. Mystical connections based in these principles, which Frazer called “homeopathic” and “contagious,” had been described since classical times, and Samuel Hahnemann had set down his principles of homeopathic medicine more than a century earlier. But Frazer elaborated on them at length and provided numerous ethnographic illustrations. Frazer made it clear that people understand the principles of similarity and contact to be operative in nature. A water-worn stone shaped like a particular fruit might be placed under a fruit tree to prompt its production. A tree or rock formation shaped like a phallus can be a source of power. Or, as

recorded by Clifford Geertz, people of the tiny island of Bali feel confident next to the far bigger island of Java because their island is shaped like a fighting cock, whereas the Javanese live on a shapeless mass and so they are weak and aimless.

Other Ritual Practices

These principles of magic and magical thinking can be seen to operate in most manifestations of a number of ritual acts and concepts: good magic, sorcery, blessing and curse, taboo and pollution, divination, and magical protection.

Good Magic

The natural order of things is good. Open, public good magic helps the forces of nature along their predetermined paths. People everywhere perform magical acts, speak persuasive words, and wear “lucky” items to increase the efficiency of the natural forces. Magic may be routine in certain economic endeavors (as Malinowski described for Trobriand gardeners and seagoing fishermen), farmers in Africa and South America employ rain charms, Aka net hunters of Central Africa sing hunting songs over their nets before the hunt or rub parts of captured animals on nets that have not caught anything for some time, and people universally employ magic in love and gambling. Magical control over game animals is a logical explanation for much of the cave art of the Upper Paleolithic, and the so-called “Venus figurines,” with exaggerated female reproductive and nurturance features, may well have been personal charms or amulets. On days when they will compete, athletes routinely wear items of clothing that they wore on days when they excelled at their sport, hoping to recreate at least part of the propitious set of cosmic interconnections that were operating on those days. In all cultures, names are intimately connected with their referents; by naming a thing, the individual exerts some control over it.

Sorcery

Sorcery is a loaded term with a great range of meanings having to do with individual manipulation of the supernatural for selfish or directly harmful ends. Referents of sorcery include invocation and command of spirits, but a generally accepted anthropological meaning of sorcery is magic. The sorcerer

employs any of the methods of magic on his or her own behalf or on behalf of the client. Sorcery is clandestine, dangerous, and universally forbidden by society for three reasons. First, it operates directly counter to the natural program by directing the forces to alter their nature or direction, and havoc can result. Second, because the amount of goodness in the world may be considered to be finite, by seeking to obtain extra wealth or advantage for oneself, sorcery automatically deprives others. Third, if sorcery aims at direct harm to another, it is a criminal act.

The best-known example of sorcery is negative image magic, as in the unfortunately termed *voodoo doll* where harm is done to the image of a victim. Some instances of sorcery are quite complex and can be understood only through specifics of the language and culture of the practitioner, but some of the principles of magic can be detected in all. The simplest form of sorcery is a curse, that is, a direct verbal expression of ill will or a similar sentiment conveyed through a gesture.

Blessing and Curse

Blessing and curse are forms of verbal expression that must be distinguished from spirit invocation, which is a totally different phenomenon. “God bless you” asks God to do the blessing and is invocation, whereas “blessings on you” and “have a good day” are blessings or direct expressions of good will. The

invocation “God damn you” asks God to condemn the target to eternal punishment in Hell, whereas “go to Hell!” is a curse because it conveys the same meaning but depends solely on the speaker’s intent and personal power and on the ability of the words to convey their meaning. Belief in the magical power of words is absolutely universal and is the basis for laws against slander and libel.

Taboo and Pollution

Taboo derives from a Melanesian and Polynesian concept most commonly meaning dangerous due to extraordinary mana. Popularly, it means forbidden by various sanctions. Magically, it means the avoidance of establishing a mystical connection by any of the principles of magic. Pollution means the conceptual “dirt” or malfunction that can result from the intermixing of powers that should remain separate, a possible result of taboo violation. Examples of both are numerous. Pregnant women should not carry pots due to the sympathetic connection to their swollen bellies, nor should they engage in acts of cutting, piercing, tying, tightening, or closing. Wives of harpoon hunters should not cut their hair while their husbands are hunting due to the symbolic connection to the strands of the harpoon ropes. The “uncleanliness” resultant from violation of any of the Jewish kosher laws, or from contact with a Dalit (a member

of India’s “untouchable” caste), is pollution. Direct intrusion of the profane into the sacred, a concern of all religions, results in pollution. Pollution can cause failure, disorder, sickness, and death.

Superstition is a term that anthropologists should avoid because it indicates superiority of the user’s knowledge; but it is clear that many popular superstitions involve avoidance of magical acts. Examples include breaking a mirror, which can damage objects reflected in it; opening an umbrella, which is an object associated with storms, in the house, which is a place of calm and order; and stepping on a crack, which is damage. at table in the Christian story of the Last Supper of Jesus, might bring about some calamity. Malinowski noted that people involved in risky or competitive enterprises routinely employ magic, including a range of taboos. In his classic article on baseball magic, George Gmelch described a player who ate pancakes for breakfast on a day he played poorly and who thereafter avoided pancakes on days he was to compete.

Divination

To discover “occult” information, one can ask spiritual agencies, and they may answer in a variety of ways. This is another example of spirit invocation. Magically, divination involves using any of the principles of magic to tap directly into the cosmic program in which there are traces of everything past, present, and future. “Reading” tea leaves, palms, the entrails of animals, or “omens” in nature is based in the assumption of cosmic interconnections. Hidden information can be elicited by the power of words, which carry their meaning into the cosmos and release the desired answers.

Magical Protection

It is universally believed that power can be abducted from any source, reformulated, and used for new purposes. Thus, the power of religious objects can repel evil that threatens a person, the contents of buildings, or activities in ritual spaces. Many such objects are cultural, but individuals can impart special powers to particular objects and behaviors. In many cases, protective magic resembles active magic, and specific cultural investigation into the intent of the maker or user may be necessary to distinguish a *charm*, which generally means an object that activates and directs magical power, from an *amulet*, which is an object that protects with a passive layer of power. For example, a rabbit’s foot, an appendage of an animal widely associated with nimbleness, speed, and reproductive power, can be either a charm or an amulet.

Explanations and Future Research

It seems clear that assumptions of causality according to the principles described in this entry are timeless and universal. Magic is evident in all areas of human endeavor and at all levels of society. The principles of magic explain why the baseball that was hit by Barry Bonds for his 700th career home run, or the baseball that was used to make the last out to win the World

Series for the Boston Red Sox in 2004, is instantly so valuable (the former sold at auction in 2004 for \$804,000); why clothes or domestic items that once belonged to celebrities fetch such high prices at auction; why the pen that a president used to sign an important bill into law becomes a collector’s item; or why the residents of an eastern American town fight to save a 350-year-old oak tree that was “witness to so much history.” Magical symbolism accompanies and enhances religious ritual. Manufacturers of pills and furnishings know that colors are popularly associated with particular actions or effects. People become accustomed to daily routines and feel disoriented and incomplete if those routines are altered. A person applies “body English” to bowling balls or billiard balls, and a passenger in a car approaching a stationary object presses his or her right foot to the floor. Examples are endless.

Social science explanations for how magic “works” are various; in healing, either the natural progression of the disease or the placebo effect is most common. Apparent failures are blamed by practitioners on various factors, but rarely on the logic of the magical practice itself. Magic has been explained in terms of its psychological functions of giving people confidence and a sense of control in a complicated and uncertain world.

Better ethnographic studies are clearly needed. In 1963, the Waxes stated that theoretical efforts had failed because writers on magic “had not truly understood how the persons in question conceived the world.” And Michael Brown’s assertion in 1986 that there is “a pressing need for fine-grained accounts of magic as it is understood and practiced in specific societies” is still valid today, and not just among traditional societies; old magical beliefs are emerging in urban market economies in developing Third World areas. The ancient and universal beliefs that certain parts of the body are loci of concentrated power have stimulated both real and imagined trades in human body parts, presumably supplied by ritual murders of immigrants, homeless people, and orphans.

But it is also clear that magical thinking is a regular, normal, and fundamental mode of cognition. It is not just New Age or neopagan enthusiasts who demonstrate magical behaviors today; everyone does. A variety of functional explanations have been given for the ubiquity of magic, but there is mounting evidence that some of the principles of magic may derive from innate instinctual tendencies. The psychologists

Carol Nemeroff and Paul Rozin conducted a series of studies during the 1980s and early 1990s indicating that ideas of contagion, the transfer of positive or negative influences by contact, are common and apparently natural. The recognition of universals in culture has long prompted anthropologists to suggest inherent biological bases for them, and today the new frontier in the understanding of magic may be the brain sciences. Symboling is at the basis of magic, and the capacity for imitation is at the basis of symboling. Neurobiological bases for the well-known imitation capability among primates were discovered during the 1990s, and recent studies by Marco Iacoboni and his colleagues at the University of California, Los Angeles, have indicated that there are bases for imitation in the cerebral cortex of the human brain.

MAGIC VERSUS RELIGION

Religion has been practiced universally from the earliest peoples until today. It seeks to connect people with a spiritual realm. Religion provides people with means for coping with the uncertainties of life and death, and it offers comfort for sorrows, healing from diseases or traumas, and peace from fears. In religion, there is often an element of faith in the appeal for help from spiritual forces to achieve peace with the powers-that-be.

Magic often accompanies religion and may be woven into some religious practices, but it is not truly a religion. Rather, magic is closer to science because its goal is power to control the forces in the world. The ultimate goal of magic is power to manipulate nature or people so as to achieve desired ends.

Magic may assume a spiritual realm and seek to use spiritual powers to help or harm other people. However, the power that is sought from the spiritual realm is not for purposes of worship but rather for control in the world. Many religions have practices that are magical in character. For example, the Navajo people use sand paintings for healing. A sand painting is symbolic of the spiritual world, and contact with it is believed to yield healing power from the spirits.

Magic, in contrast to religion, is concerned with power over nature, people, or things. Magic assumes that there are causes and effects in the world that are knowable or achievable. It also assumes that contacts can cause effects. If a magician manufactures a chemical concoction that will cause the recipient to fall in love, this is an action based on a belief in causality. The assumption of magic that there are causes and effects in the world produces homeopathic (imitative) magic. A common example of imitative magic is the voodoo doll (*envoutement*), which resembles the person who the magician wishes to control or harm.

The second assumption, that contacts can cause powerful effects, produces contagion magic. Contagion magic operates on the belief that contact with something will give power that can be used to do things or to harm someone or achieve some other goal.

Magic, as it is practiced in some “primitive” societies, may use rituals, material means, and psychological means to achieve its effects. Magic may use rituals to cause gardens to grow, to overcome the uncertainties and dangers of open-water fishing, or to empower a protective “shield” around a canoe or a person.

Most “magicians” in contemporary Western societies are illusionists who entertain with sleight-of-hand or trick devices. Although they act mysterious, their magic is based on deceiving the eyes of the audience members.

MAINE, HENRY SUMNER (1822–1888)

With his ideas influencing lawyers, historians, sociologists, and others, Sir Henry Sumner Maine’s writings on law have been extremely influential. Maine, a comparative jurist and historian, is noted for developing comparative studies of law and for focusing on law among indigenous populations.

Maine’s notable achievements in the study of law include leading people to situate the study of law in its social and historical setting and noting that changes in laws reveal changes in society at large. Maine believed that all societies evolved from having customs to having laws. In his writings, he arranged the laws of ancient societies to try to develop and confirm a standard process of the evolution of legal and political systems. In *Ancient Law* (1861), Maine’s most popular work, ancient laws were examined as an attempt to learn the earliest human belief systems and relate these beliefs to those of modern humans. Maine developed the theory that traditional societies were based on status (personal rights based on kinship or other relationships), whereas modern societies are based on contract (rights based on written ethics). In one of Maine’s later publications, *Popular Government* (1885), he outlined his theory that democracy is not necessarily more durable than other forms of government. Moreover, Maine argued that democracy does not inevitably lead to development.

Maine began attending Pembroke College, University of Cambridge, in 1840. His honors include

the Craven scholarship and senior chancellor’s medalist in classics, and he graduated as senior classic in 1844. Maine became a junior tutor at Trinity College, Cambridge, in 1845. He was named Regius professor of civil law at the University of Cambridge in 1847 and remained in that position until 1854. In 1850, he was called to the bar and held this position until 1854. He also lectured on Roman law at the Inns of Court, London, and was an original contributor to the *Saturday Review*. Maine was then offered the post of legal member of council in India in 1862. Although he turned it down the first year, he accepted the offer when the post was again vacated the following year. In this position, Maine acted as adviser to the government of India on both political and legal issues. He also worked as the vice chancellor of the University of Calcutta. Maine remained in India until 1869, when he returned to the University of Oxford to the position of chair of historical and comparative jurisprudence. Maine became a member of the secretary of states council in 1871 and remained in that position until his death in 1888. In addition, in 1877 he was appointed mastership of Trinity Hall, Cambridge, and then in 1887 he became the Whewell professor of international law at Cambridge.

HENRY SUMNER MAINE

Sir Henry Sumner Maine was a jurist and an early student of primitive law. He wrote several important books on ancient laws and was a pioneer in the method of historical and comparative study

of institutions. He influenced many scholars with the idea that law and legal institutions must be studied historically.

Maine was born on August 15, 1822, in Roxburghshire, England. He attended Pembroke College at University of Cambridge, where he flourished as a classical scholar. In 1847, Maine was appointed Regius professor of civil law at Cambridge. He was admitted to the bar in 1850. In 1852, he was appointed as a reader to the Inns of Court. In 1861, he published *Ancient Law* based on his research and lectures before the Inns of Court.

The goal of *Ancient Law* was to present some of the earliest ideas people have had about the conduct of human relations. In addition, Maine attempted to show the relationship among ancient ideas, Roman civil law, and modern thought. Maine argued that people worked with one another in civilized society due to consent, tradition, inertia, and/or mutual advantage rather than force. This meant that civilization rests on contract-like agreements rather than on status.

In 1862, Maine was offered a position as a legal adviser to the consul in India. Declining the offer at first, he soon sailed for India, where he eventually advised the government of India on a number of issues and also prepared the way for the codification of Indian law. In 1869, Maine returned to England. Thereafter, he held a number of teaching positions before being elected master of Trinity Hall in 1877. In 1887, he was named Whewell professor of international law.

Maine's lectures on legal history, given at Oxford and Cambridge, were put into several books, including *Village Communities in the East and the West* (1871), *The Early History of Institutions: Lectures on the Early History of Institutions* (1875), *Village-Communities in the East and West* (1871), and *International Law* (1887). *Village-Communities in the East and West* dealt with Indian law, Islamic law, feudalism, enclosure, family, usury, land, and other laws.

Maine died February 3, 1888, in Cannes, France. Some of his ideas have since been rejected as erroneous. However, he has had a great impact on the study of jurisprudence from a historical perspective in early and modern societies.

MALINOWSKI, BRONISLAW (1884–1942)

Bronislaw Malinowski has been called the Joseph Conrad and Rider Haggard of anthropology, reflecting both his “romantic fascination with the culturally exotic” and a career that found him working from the South Seas to Mexico—to say nothing of the halls of the London School of Economics where he taught for more than 20 years. Considered to be the father of modern anthropological fieldwork, Malinowski trained two generations of ethnographers and guided the direction that British social anthropology was to take for decades.

Malinowski was born in what is now Kraków, Poland, on April 7, 1884, to a well-to-do academic family. He

received his Ph.D. in physics and mathematic from Jagiellonian University in 1908. He read James Frazer's *The Golden Bough* in English while recuperating from an illness, and his interests in anthropology, psychology, and folklore blossomed. He studied with the famous psychologist Wilhelm Wundt for three semesters at Leipzig and went on to the London School of Economics, one of Europe's centers of anthropology, before World War I (receiving a D.Sc. there in 1916 on a library study written in 1913).

At the start of World War I in 1914, Malinowski was traveling back and forth between Australia and various field sites. Technically being an enemy alien in British Commonwealth territory, he could have been arrested but instead was allowed to continue his fieldwork in the Trobriand Islands off the coast of New Guinea for some 2 years. This fieldwork was the basis for much of the classic Malinowski canon, including his most famous works *Argonauts of the Western Pacific* (1922), *Crime and Custom in Savage Society* (1926), *Sexual Life of Savages* (1929), and the two volumes of *Coral Gardens and Their Magic* (1935).

Malinowski is most well known for his major contributions to anthropological theory. Functionalism, in the sense that he used the term, sees every social institution as existing to satisfy one of seven basic needs of the individual: nutrition, reproduction, bodily comforts, safety, relaxation, movement, and growth. The task of the functionalist is to show how cultural beliefs and practices not only smoothly integrate society but also offer psychological and biological sustenance for the individual.

Although Malinowski is not as well known as his work in social anthropology, his contributions to linguistics were also significant. He included, for example, an extensive essay on the role of language in *Coral Gardens*. In addressing issues of translations of Trobriand magic chants, he argued that none could actually be made because they had no real semantic content. Nonetheless, these chants accomplished

tasks in Trobriand society, such as ensuring a plentiful harvest and indicating who had rights to certain gardens, even though the chants were meaningless. Malinowski's idea of "phatic communication"—that some language is used to maintain social contact rather than to exchange meaningful information—is still an important concept in sociolinguistics.

Malinowski became a visiting professor at Yale University in 1940, but lingering poor health took his life in 1942. As important as he was, Malinowski was not without faults or detractors. He was sometimes prone to self-promotion, his relationships with women were occasionally tumultuous and much discussed, and some considered his theoretical perspectives to be mere biological reductionism. The posthumous publication of his private journal while in the Trobriands, *A Diary in the Strict Sense of the Term* (1967), and letters to his wife, *The Story of a Marriage: The Letters of Bronislaw Malinowski and Elsie Masson* (1995), revealed some of Malinowski's all-too-human thoughts of both informants and colleagues. But his place in the history of anthropology is ensured. If nothing else, the scores of students he trained, including Raymond Firth, E. E. Evans-Pritchard, Meyer Fortes, Lucy Mair, Ian Hogbin, and Hortense Powdermaker, ensure that nearly every anthropologist today is a Malinowskian functionalist, at least in some way.

MALTHUS, THOMAS (1766–1834)

At the end of each day, the world has more than 200,000 more mouths to feed than it had the day before; at the end of each week, it has 1.5 million more mouths to feed; and at the close of each year, it has an additional 75 million mouths to feed. In the world's poorest countries, where population growth is most rapid, the lives of hundreds of millions of people are constantly plagued by hunger and by diseases aggravated by malnutrition. Humankind, entering the 21st century, now numbers well over 6 billion and is caught in an ambush of its own making. Economists call it the "Malthusian trap" after the man, Thomas Robert Malthus, who stated our grim biological predicament most forcefully: Population growth tends to outstrip the supply of food.

Malthus was born in a country house near the town of Dorking, England, the son of a gentleman who prided himself on his advanced ideas and who was an admirer and friend of both Hume and Rousseau. Young Robert (he was never called Thomas) was at first privately educated. In 1784, he went to Jesus College, Cambridge, where he graduated creditably as Ninth Wrangler (an honors degree in mathematics) in 1788. In that same year, he took holy orders and later was appointed to a rectory. In livelihood, however, he was less a "parson," as his detractors have often chosen to call him, than a college professor, for in 1805 he became the first professor of political economy in the English-speaking world at the new East India College in Hertfordshire, a post he held until his death in 1834. He published his controversial book, *An Essay on the Principle of Population as It Affects the Future Improvement of Society*, anonymously in London in 1798 and brought out a greatly enlarged edition in 1803.

Eighteenth-century thinkers had tended to view population growth as a mark of social well-being; an increase in people was generally taken to imply an increase in wealth. Malthus saw it differently. He began with the awesome redundancy of nature: "Through the animal and vegetable kingdoms," he wrote, "nature has scattered the seeds of life abroad with the most profuse and liberal hand." On the other hand, he asserted that nature "has been comparatively sparing in the room and the nourishment necessary to rear them." It follows that the tendency of populations to multiply, if unchecked by other means, will eventually be checked by starvation; the number of people will simply (and, of course, only temporarily) outstrip the supply of food. This is the most brutal and final of "positive" checks to population growth.

As a former mathematics student, Malthus could not resist a mathematical illustration. He wrote that population can increase geometrically, whereas agricultural production can increase only arithmetically. So, while the population grows "in the ratio of 1, 2, 4, 8, 16, 32, 64 . . .," subsistence will increase only as 1, 2, 3, 4, 5, 6, 7, and so on. That was a persuasive argument, although only the first part of it was true on its face; the reproductive potential of any plant or animal species verifies it. Both Charles Darwin and Alfred Russel Wallace, impressed with Malthus's argument, found in it the key to the theory of natural selection. Darwin, 2 years after his round-the-world voyage on the *Beagle* and puzzling over the origin of species, happened to read Malthus's essay ("for amusement") and was immediately struck with its relevance to his problem. "A struggle for existence," Darwin wrote in *On the Origin of Species*, "inevitably follows from the high rate at which all organic beings tend to increase. . . . It is the doctrine of Malthus applied with manifold force to the whole animal and vegetable kingdoms." Darwin reasoned that if more organisms are born than can possibly survive, it will be the best adapted or "fittest" variants that do survive, and with enough new variants over a long period of time, new species could evolve. The second part of Malthus's proposition was problematical because Malthus, depending on his observations of the agricultural practices of the late 18th century, did not foresee the increased food production that would follow the industrial revolution. For more than a century after Malthus's death, food supplies increased far more rapidly than he had predicted. But during the post-World War II period, when antibiotics and other

medical and health improvements caused huge population increases, food supplies would again be inadequate to provide for the world's hungry and malnourished. No doubt, Malthus would now feel vindicated by history.

The earnest effort of many governments to encourage birth control, together with a new self-reliance among better-educated women in the developing countries (and thus their acceptance of family planning), has helped to bring total world growth rates down somewhat during recent years. But birth control information and assistance are not available everywhere, and this is one reason why global growth rates are still ominously elevated. Realistic mid-range projections show world population increasing from 6 billion in the year 2000 to 9 billion by 2050—a 50% increase in only 50 years. Such rapid growth, so long continued, is causing human demands to overshoot not only the world's finite resource base but also its environmental carrying capacity, with potentially tragic results for our own generation as well as future generations.

Environmental overload is already causing dramatic losses of much-needed cropland due to salination, waterlogging, and erosion as well as to urban sprawl, road building, and other effects of larger populations. Rangeland and fisheries are also being exploited beyond their capacity for recovery. Meanwhile, 1 billion of the world's 6 billion people are chronically malnourished, and in densely populated countries such as India, Bangladesh, Pakistan, Ethiopia, and Nigeria, where half of the children are already undernourished, hunger continues to increase as populations grow. Water shortages are a part of the population–food equation that could hardly have seemed troubling to Malthus, living in a country of plentiful rainfall. But freshwater shortages may well be the most severe threat of all, not only to the human need for potable water but also to the needs of industry and agriculture. As populations grow, the demands for freshwater supplies of all sorts—surface water, groundwater, reclaimed water—are increasing. Meanwhile, many ancient aquifers (which are mainly “fossil water” deposited over many centuries) are being overpumped for irrigation and are in danger of nearly total depletion in the foreseeable future, threatening food production on irrigated lands. And irrigation itself, on which so much of world food production depends, can have deleterious aftereffects that eventually make the soil virtually worthless for agriculture.

Population growth also causes energy-related problems such as air pollution, global warming, depletion of fossil fuel supplies, and destruction of the ozone layer. These detrimental effects are due partly to voracious fuel consumption in the industrialized societies, but they are also due to the huge increase in energy demands required to double or triple food supplies during this century so as to feed the world's burgeoning population more equitably and adequately. This disparity between increasing energy demands and diminishing traditional energy supplies has prompted a close look at newer or alternative (and less polluting) energy sources, including wind, solar, hydro, geothermal, and hydrogen power. All of these, however, are still in the early stages of commercial development.

Overpopulation also burdens and stresses the environment. It is increasingly clear even to casual observers that dense populations degrade the long-term carrying capacity of the earth. The wealth of the earth is far less a matter of gold and silver than of fertile soil, forests, fisheries, fresh water, and clean air; these are the assets that sustain our lives and undergird

our civilization. But that fundamental wealth is being depleted by a global population that is too numerous and too wasteful.

Various kinds of social disruption are also caused by population growth. Disputes over inadequate supplies of food, water, and other resources can destabilize governments, cause civil strife, and degenerate into social chaos. Meanwhile, preexisting religious or ethnic conflicts can be exacerbated by ongoing demographic pressures, causing riots, massacres, and “ethnic cleansing.” They may also spur large-scale emigration to neighboring countries that are often hostile to such massive immigration. Rapidly growing populations can also breed international conflicts over shared or common resources such as water, and these conflicts have implications for other nations, often far removed from the locations of the struggles. In 2002, Thoraya Obaid, head of the United Nations Population Fund, pointed out that rapidly increasing populations in the Middle East have resulted in very high proportions of young people there, and many of them are radicalized by “a growing sense of inequality and injustice” that, she warned, leads to extremism and terrorism. “There is no doubt,” she said, “that demographics and population are linked to political instability,” and she called for improved family planning services, health services, and education.

From the very beginning, Malthus’s message was greeted with widespread hostility, and that antagonism has continued to the present day. Criticisms now come chiefly from those holding left-leaning social ideas or right-leaning capitalist doctrines or from those with religious objections to birth control. The critics operate on the assumption that despite the population explosion of the past half century, all is well nonetheless. They simply assert that there is no population problem, that overpopulation does not cause hunger, that all of the talk about overpopulation is only a mask to conceal capitalist—or socialist—failures, and that the world and its natural resources are, for practical purposes, infinite. However, the desperate conditions in much of the Third World today refute these ideas.

Another obstacle to sensible population limitation is the hierarchy of the Roman Catholic Church, which condemns birth control, calling it “an offense against the law of God and of nature.” Most other religions disagree with this opinion, but the Catholic hierarchy, wielding the political power of large congregations,

continues to oppose population limitation. Its influence is especially unfortunate in the United Nations, where for many years it has succeeded in weakening or preventing family planning programs despite the current suffering in the Third World and the severe hardships that continuing overpopulation will inevitably bring to people everywhere.

Complicating this picture is the Catholic hierarchy’s associating birth control with abortion so that U.N. population programs can be further undermined by the accusation that they promote abortion—even when that is not true and even though birth control has been shown to prevent large numbers of abortions. On the abortion issue, the Catholic hierarchy is joined in an unlikely alliance with certain American fundamentalist Protestant groups. Together, with their strong influence on conservative politicians, they have successfully pressured several administrations in Washington, D.C., to ignore the global population problem and to withhold family planning contributions to the United Nations. When Malthus died in 1834, the total population of the world barely exceeded 1 billion. If he were to return now in the 21st century, he would find a world population that is well over 6 billion. He would be surprised at that because he would find it hard to believe that food supplies had increased sufficiently to keep so many people alive. He would be far less surprised to hear that of those 6 billion people, 1 billion of them—as many as existed in total during his own time—are suffering from malnutrition and in danger of starvation. So, despite two centuries of progress in agricultural productivity, there is little in today’s world situation that would cause Malthus to change his mind. In many Third World countries, there is simply not enough locally grown food to nourish the population adequately, and food from foreign sources is increasingly expensive and unaffordable due largely to the high costs of oil and fertilizer. Meanwhile, the world population keeps growing by 75 million mouths per year. Because of rapid population growth, humans everywhere face a future of uncertainty and prodigious challenge. But the same man who anticipated our current predicament also prescribed the only tenable response to it. As Malthus wrote, “Sufficient yet remains to be done for mankind to animate us to the most unremitted exertion.”

Mana is the Polynesian and Melanesian concept of communicable supernatural power. This is a variant of a probably universal belief in a power that exists to varying degrees in things in nature. In most cultures, it is believed that the power is vital for the interactive participatory role of things in an interconnected cosmos, but in great concentrations it can be dangerous. It is stronger in animate things than in inanimate things, and it is stronger in higher order things than in simpler things; people have more mana than do animals; and in kings and spiritual beings, its intensity is dangerous to ordinary people. Mana is, indeed, the essence of sacredness or holiness.

It is because their communicable mana is so intense that Polynesian kings were veiled and carried, and because one's shadow is an extension of oneself, care was taken that kings' shadows did not fall on ordinary citizens. The personal attendants to Polynesian kings were obliged to submit to magical rituals to remove the potentially harmful royal mana from their hands when their services were ended. In Melanesia, the intensity and dynamism of mana may vary among members of the same class of things, so fishermen or hunters will treat carefully the particular fishhook, net, or spear that seems to be especially efficient, and

if it loses its power, magical rituals will be enacted to strengthen it.

Mana-like Power Elsewhere

If supernatural beings are conceptualized as ranked hierarchically in a society, gods will have more power than other kinds of spirits and the Supreme Being will have the greatest concentration of power. The intensity of divine power is illustrated in the biblical concept of God's "glory," famous as the cause of the shepherds' terror in the Christmas story. In Exodus, Moses asks God to reveal Himself, but God replies, "You cannot see my face, for no one can see me and live"; nevertheless, when Moses came down from the mountain, his people were frightened because his face was shining from being so close to God. Subsequently, after his talks with God, Moses veiled himself to protect his people from the contagious divine power.

Some well-described cultural concepts of mana-like power include Iroquois *orenda*, Algonquian *manitou*, Sioux *wakan*, Malay *kramat*, Indian *brahma*, Greek *dynamis*, Chinese *qi*, West African Yoruba *àshé* and its Caribbean derivatives (*aché* and *axé*), Islam *baraka*, Hindu and Buddhist healing systems' *karma* and *chakras*, the alleged "energies" in Therapeutic Touch and Reiki, and ideas of flowing streams of power in the earth such as "leylines" in Britain and Europe and variants of *qi* as earth energies addressed in the Chinese geomantic system of feng shui. For reasons similar to those in Polynesian monarchies, some African kings were veiled, carried in public, and otherwise separated from commoners. In popular use today, the term *mana* sometimes means an inherent power to bring good luck or good health. New Age adherents to the health food movement of the 1970s and 1980s regarded some "natural" foods as containing mana, charged with a beneficial life force, whereas certain sugary or processed foods were taboo and harmful. In Melanesia, found rocks or other objects with unusual or suggestive shapes might be presumed to have beneficial mana and would be used magically. Similarly, the southern U.S. African American concept of *mojo*, as a beneficial power vested in certain things and behaviors, is a mana-like concept.

Mana in Anthropology

The mana concept seems to have been brought to the attention of anthropology by Robert H. Codrington,

a missionary in Melanesia from 1883 to 1887, and it has been important during various stages of the history of the discipline. Continuing the late 19th-century inquiries into the development of religion, in his 1909 work *The Threshold of Religion*, R. R. Marett presented mana as a more basic concept than a belief in spiritual beings and thus was prompted to propose what he called “animatism” as a precursor to the “animism” proposed by E. B. Tylor as the earliest form of religious beliefs. Marcel Mauss and Henri Hubert used mana as the basis for their 1902–1903 construction of a “general theory” of magic and were later criticized by Claude Lévi-Strauss and others for generalizing from a culture-specific concept.

Herein lies a caution, indicated by various scholars over several decades: Generalizing about mana might violate a fundamental premise of anthropology. Anthropologists emphasize that culture-specific emic concepts might not be transferable to other cultural systems. As E. S. C. Handy’s ethnological research (e.g., *Polynesian Religion* in 1927) showed, the concept of mana is superficially similar across Melanesian and Polynesian cultures, but it differs in important ways. For example, in Melanesia people seek mana and work to increase it, whereas in Polynesia mana is more dangerous and unprotected commoners are wary of it. Moreover, within each area, it might not be identical from one culture to another. In some places mana is hereditary, in some it is conferred, in some it is acquired, and in some it occurs naturally and may or may not be ritually strengthened or weakened. In both culture areas, dangerous quantities of mana render something taboo (*tabu*, *tapu*, or *kapu*), that is, to be avoided lest one suffer injury or become polluted. But the nature of the danger and of its contagion, as well as protection against it and ritual remedies for it, may vary in different places.

And mana can be evil. Handy noted that mana may be intentionally used in destructive ways. By the same ritual process that beneficent mana is increased, the power of a “necromancer’s familiar” in Hawaii is “raised to the power of a malicious demon” that presumably can be sent to attack one’s enemies. Sorcerers are described as having “great mana for causing sickness and death . . . evil mana, diverted and at work against man’s life and well-being.” In Africa, it is often a corrupted form of the personal power that becomes witchcraft or purely evil; a well-known example is the Yoruba àshé, which is the basis for the dreaded witchcraft power àjé (no etymological connection).

In Polynesia, the system of mana and tabu correlated closely with and obviously helped to define the hierarchical social structure. Other social, political, or cosmological functions might be deduced elsewhere. Similarly, the mana-like concepts described earlier for other cultures are superficially similar, but in specific details they may vary importantly from one culture to another. Each culture’s concept should be described in its own terms before cross-cultural comparisons can legitimately be made; and even the phrase “mana-like” might be inappropriate.

MANIOC BEER

A mild fermented alcoholic beverage made from the starchy root of manioc, *Manihot esculenta*, is a domesticated woody perennial shrub. Consumed in generous quantities, particularly during feasts and rituals, it has been a significant item in the diet of native tropical South Americans since pre-Columbian times. Adults and children alike drink it. The beer is known by different names (e.g., *yarake*, *kashiri*, *chicha*, *masato*).

Manioc beer can be prepared in different ways to change its taste and alcohol content. Manioc tubers can be peeled, boiled in water, and pounded to make a mash, or they can be peeled and grated and the

resulting pulp can be boiled. Sometimes the tubers are placed in a dugout canoe with water for several days to soften before boiling. Toasted manioc cakes, instead of fresh tubers, are also employed. Although the beer can be made with manioc only, other items are often added to the boiling pot, including one or more varieties of sweet potato, maize, pineapple, and sugar cane. To promote fermentation, boiled manioc or sweet potato is chewed and added to the mash. The mash is then left to ferment for several (at least 2–3) days in a dugout canoe or, more frequently today, in some huge plastic container such as a garbage can. The alcohol content increases with the length of fermentation period. Some native groups will further enhance the beer's alcohol content by adding sugar cane rum, a practice that is related to the introduction of rum into native areas. To drink the beer, water is mixed with the mash, which is then strained through a sieve. Some groups (e.g., the Campa of Peru) follow a strict etiquette when serving the beer. In several groups, women will serve both male and female guests; in others, males will serve males and females will serve females.

Prepared by women and shared beyond the nuclear family or household level, manioc beer highlights camaraderie based on food sharing and the exchange of products between the sexes. In many native groups, manioc beer is given to those who participate in collective work such as the clearing of a garden. Women are frequently judged on their ability to make this beer. Similarly, the quality of feasts is appraised by the amount and excellence of the beer. Although manioc beer is still made and drunk in prodigious quantities by various groups, the art of making manioc beer has been in decline. In the past, women prepared many types of manioc beer (e.g., the Taulipáng made nine types) by using different varieties of both manioc and added crops, mixing other ingredients such as ash, and exploiting different processing methods (e.g., allowing fungi to decompose the toasted manioc bread that is used). Today many women do not know about, or have never employed, these diverse methods of preparation. This is related to the decline of traditional rituals and feasts often brought about by participation in economic and political activities that detract from communal living and sharing, as well as to the proselytizing of Christian missionaries, among other reasons.

MANN, THOMAS (1875–1955)

Paul Thomas Mann was born on June 6, 1875, in Lübeck, Germany, and died August 12, 1955, in Zurich, Switzerland. He wrote numerous novels, novellas, and essays and was awarded the Nobel Prize for Literature in 1929.

Mann's parents, Julia née da Silva Bruhns and Thomas Johann Heinrich Mann, belonged to the wealthy Lübeck bourgeoisie. Thomas was the second of five children. His older brother Heinrich also became an important author. After his father's death and the liquidation of the family firm in 1891, his mother moved with the three younger children to Munich while Thomas stayed at school in Lübeck. In 1894, he followed his mother to Munich and began to work for an insurance company but quit after 4 months. During this time, he wrote his first story, "Fallen" (*Gefallen*). During the same time, he attended some lectures at the Technical University of Munich, his only academic education. In 1898, the story collection *Little Herr Friedemann* (*Der kleine Herr Friedemann*) was published, followed by Mann's first novel, *Buddenbrooks*, in 1901. In his novel, Mann described the decline of the family Buddenbrook that was inspired by his own family's history. The financial decline was associated with an unfolding of aesthetic sensibility. The opposition between art and *Bürger* (the middle classes/bourgeoisie) was one of Mann's main themes, especially in his early works, and also was taken up in his novellas *Tristan* and *Tonio Kröger* in 1903.

In 1905, Mann married Katia Pringsheim, who belonged to a wealthy family of Jewish descent. The

couple had six children. Mann's second novel, *Royal Highness* (*Königliche Hoheit*), was published in 1909. After some difficult years of low productivity, his novella *Death in Venice* (*Tod in Venedig*) was published 1912.

In reaction to World War I, Mann wrote his voluminous essay "Reflections of an Unpolitical Man" (*Betrachtungen eines Unpolitischen*) in 1918. In his novel *The Magic Mountain* (*Der Zauberberg*) in 1924, he showed the decline of the bourgeois world of the 19th century by describing the stay of Hans Castorp, a young engineer from a wealthy family, in a sanatorium in Davos, Switzerland. In 1929, Mann was awarded the Nobel Prize for Literature. In 1930, his story "Mario and the Magician" (*Mario und der Zauberer*) depicted the psychology of fascism using the example of a family's holiday experiences in Italy. Twelve days after Adolf Hitler became chancellor of Germany in 1933, Mann left Germany for a lecture journey and did not return. After visits to several countries, he settled in Switzerland. In 1933, the first part of his tetralogy about "Joseph and His Brothers" (*Joseph und seine Brüder*) was published, and the last part followed in 1943. This epos described the biblical mythos of Joseph in a psychological perspective. In 1936, Mann became a citizen of the Czech Republic and was deprived of his German citizenship. In 1938, he settled in the United States, where he taught German literature at Princeton University. In 1939, he finished his Goethe novel *Lotte in Weimar*, which gave a psychological portrait of Goethe and his environment. *Doktor Faustus*, published in 1947, described the life of the composer Adrian Leverkühn as told by his friend Zeitbloom in Germany during the end of World War II. The novel dealt with the problems of Germany's intellectual identity. Mann's final novels, *The Holy Sinner* (*Der Erwählte*) and *Confessions of Felix Krull*, *Confidence Man* (*Bekenntnisse des Hochstaplers Felix Krull*), were published in 1952 and 1954, respectively. Alarmed by the anti-Communist hysteria of the Joseph McCarthy era in the United States, Mann moved to Switzerland in 1952. His final work was his essay on Friedrich Schiller in 1955. Mann died that year in Zurich.

Mann did not have any explicit anthropological theory of his own. Nevertheless, his work contained an artistic adaptation of the intellectual discussions of his time, strongly influenced by the thoughts of Nietzsche, Schopenhauer, and Goethe but also by Kierkegaard, Paul, Schiller, and others. His novels

and many of his essays reflected on the problems of human existence.

Characteristic of Mann's style was a distance from his subjects that he took by using humor and irony. Irony for Mann was the reconciliation of life and spirit. The opposition between life and spirit mirrored Nietzsche's conviction that life must be taken affirmatively. Mann denied this thought and united Schopenhauer's pessimism with it. In this new conception, life was still unchangeable, but the spirit was not an affirmative one; rather, it denied life by taking an ironic view of it.

The Magic Mountain was representative of Mann's intellectual novels, all of which reflected on the nature of humankind. In this novel, Hans Castorp, a young engineer, visits his cousin in a tuberculosis sanatorium in Davos and stays for 7 years, fascinated by the morbid atmosphere of this magic mountain (the title is an allusion to the Walpurgis Night in Goethe's *Faust*). Castorp is drawn in by the atmosphere and patients and is immersed in a struggle for cognition about the world. The novel circles around the main themes of the intellectual debate of the time, the great questions of humankind—life and death, reason and emotion, and time. Castorp is fascinated by the eros of dying but tries to fight it on lonely ski walks in the dangerous Alps. Reason is symbolized by Settembrini, an Italian freemason and democrat, but is defeated by the erotic attraction of Clawdia Chauchat. After his sexual experience with her, Castorp finally gives up his work ethos. In *The Magic Mountain*, and in all of Mann's other stories, humans are threatened by dark instincts or mysterious forces (e.g., by overwhelming sexuality) that destroy their orderly lives.

Time is of no importance in the magical atmosphere of the mountains, where people seem to live without time and everything runs in big circles. In this motive, Mann took up Nietzsche's idea of the eternal recurrence of the same. After Chauchat's departure, two more characters fight for Castorp's "soul." Naphta, Settembrini's antagonist, is a Spanish Jesuit whose ideology is a mixture of Christian mystics, communism, and totalitarianism. In opposition to Settembrini and Naphta is Pieter Peeperkorn, who is not very intelligent but is very attractive in his vitality. Peeperkorn's impressive personality wins this conflict without any fight. Finally, Castorp finds the synthesis of all polarities—love and goodness—in a dream but fails to understand the dream when he

awakes. He and the whole environment disappear during World War I.

Māori tribes today commemorate in song and dance how their ancestors came to the North Island of New Zealand in seven canoes (*waka*). Believed to have arrived from the Society Islands in central Polynesia during the middle of the 14th century, they escaped warfare and excessive demands for tribute. The migrants assimilated indigenous inhabitants—hunters, fishers, and gatherers of the same Polynesian stock who had arrived earlier in 950 and 1150 and named the land *Aotearoa* (“The Land of the Long White Cloud”) for mists visible on the mountains.

In 1947, the Norwegian explorer Thor Heyerdahl drifted across the Pacific from the coast of South America on the *Kon Tiki* in an attempt to show that the first people to arrive might have come that way. In spite of Heyerdahl’s successful voyage, scholars believe that the original Polynesians came from the mainland of Southeast Asia. With navigation skills equaling those of the Vikings, they ventured north to Hawaii, west to Easter Island, and south to New Zealand, where they were called Moa Hunters due to the large flightless birds they found there and hunted to extinction. The Moa Hunter harpoon is similar to a prototype found in the Marquesas, whereas the minnow shank lure is a stone copy of the Polynesian pearl shell bonito lure found in other parts of Polynesia.

The Polynesian migrants of 1350 introduced an agricultural economy and competition for open fertile land suitable for cultivation to supplement the hunting with spears and snares; fishing with lines, nets,

and traps; and gathering of shellfish, berries, roots, shoots, plant stem piths, and fern roots already practiced. Available protein included fish, shellfish, seals, rats, and birds. The migrants brought plants to grow for food, and several of these plants did not survive the transition from a tropical climate to a temperate one. Taro, yam, gourd, and sweet potato (*kumara*) did. The paper mulberry plants the migrants brought thrived only in the warmest part of North Island.

Cultivation of plants led to a more settled way of life, cooperative work, and a denser population. Men felled trees; cleared ground; planted; trapped rats; dug roots; fished; hollowed trees for canoes; performed rites; carved bones for fishhooks, ornaments, and spearheads; tattooed faces and bodies of men as well as ankles, arms, lips, and chins of women. They also made adzes of greenstone jade and flake knives of obsidian along with wedges, skids, lifting tackles, fire ploughs, and cord drills for tools. Women gathered; weeded; wove; collected firewood; carried water; cooked; and plaited flax for clothes, cords, baskets, and rain capes. Slaves taken captive did undesirable jobs. Sea and agricultural products were exchanged for forest products, and greenstone from the South Island was traded for finished goods from the North Island.

As life became more comfortable, carving and other decorative arts began to include elaborately decorated cloaks for persons of rank, prows of canoes, gateposts of villages (*pas*), and fertility symbols (*tikis*). A beautifully carved war canoe could add greatly to a tribe’s spiritual force and status (*mana*), an attribute that could be inherited or acquired.

The greatest change in Māori culture after the arrival of the canoes in 1350 was the progression from a peaceful society toward a warlike one as population and land pressures increased. The earlier Polynesian culture had had no weapons of war or fortifications of any kind. Once the migrants of 1350 arrived, Māori developed an extensive array of palisade forts and wood, bone, and stone clubs. People migrated from open unfortified settlements (*kainga*), consisting of several scattered houses with a cooking shelter, earth oven, and roofed storage pit, to fortified enclosures (*pa*) in which houses were crowded together. Pa were built on terraced hilltops with concentric walls and elaborate ditches, fighting platforms, and earthworks to withstand spears.

The first contact with Europeans occurred in 1769 when Captain James Cook visited the 200,000 to 250,000 Māori of New Zealand. The pig and the

potato, his gifts, became currency for barter when Māori wanted steel tools, blankets, and muskets from European traders and unfriendly whalers and sealers during the 1790s. Māori protected missionaries, who arrived in 1814, as well as ex-convicts and ship deserters because they were intermediaries when chiefs wanted to trade with visitors.

Cultural change became rapid after 1820 when young men who had worked on ships returned after having acquired new possessions and diseases. The status they had achieved challenged the hereditary privilege of chiefs. In addition, large numbers of Europeans and Australians who began to arrive by the 1830s had no regard for the laws of sacredness (*tapu*). Furthermore, the priestly *tohunga* could not compete with the status of teachers trained by missionaries. Māori questioned whether traditional beliefs were valid. The power of chiefs, those descended from the oldest males of each generation with status, was further undermined when missionaries insisted that they put aside wives and free slaves as prerequisites for baptism.

With the Treaty of Waitangi, signed in 1840 by 500 indigenous chiefs, the Māori gave sovereignty to the British in exchange for recognition and protection. Rapid enculturation followed. From 1860 to 1865, Māori battled with the government of New Zealand over questions of land rights and sovereignty. Britain ultimately confiscated 3 million acres of Māori land. Intertribal warfare was more deadly than before due to muskets that Māori had acquired, and their population fell to 42,000 by 1896.

By 1900, the population began to increase as Māori took a more active role in society, receiving permanent seats in the national legislature. Most discriminatory laws were repealed. Health, housing, and education policies were reformed. Arts and crafts were revived by 1940. Since the 1960s, Māori have struggled valiantly to maintain a distinct culture and identity as urban dwellers. In 1995, the queen apologized for “wrongful and unjust” confiscation of their lands and made reparation. Legally recognized as a minority, Māori receive special legal and economic considerations.

Traditionally, the nuclear family (*whanau*) of a descent group possessed rights to resources and land that could be passed to members’ children. Nonmembers had to seek permission of an entire descent group. Conquest was a legitimate way of gaining access to food or land, equal to ancestral right or prior discovery. Even though loss of life was probably negligible from primitive weapons in battles shortened by the demands of the growing season, constant threat of attack made it important to own land communally. Local border disputes continued from the middle of the 16th century.

Battles to avenge insults or extract retribution became one of the best ways for a tribe to promote its *mana*. War had its own worship, sacrifice, ritual, dance, and art forms. Losers often became slaves or food; cooking and eating an enemy delivered the ultimate insult.

A person’s brothers and maternal and paternal cousins all were called “brothers.” A person’s sisters and cousins all were called “sisters.” Children were desired, and adoption was frequent. Children were

educated by relatives, particularly grandparents, with songs, stories, and competitive games to imitate adult activities. A Māori child had as many mothers as his or her biological parents had sisters. An extended family, the basic social unit, consisted of an elder, his wife, their unmarried children, and their married sons and their families. Divorce was commonplace and required no more than a simple agreement by two partners to end the marriage. Population control was accomplished by means of abortion, infanticide, and postpartum sexual abstinence.

The largest kin groups were 50 independent political tribes (*iwi*) occupying particular territories. Iwi whose ancestors arrived in the same canoe felt obligated to help one another. Marriage partners, chosen by senior members of the whanau, allowed new relations to be established with other kin groups and brought new members into the subtribes (*hapu*) in each iwi. Aristocrats such as chiefs usually betrothed their children as infants. Aristocratic females brought gifts of land and slaves to marriage. Marriages were monogamous, but chiefs took several wives. Marriages were usually between members of the same tribe, frequently between members of the same hapu, but never between first and second cousins. Commoners exchanged gifts when they married. Rank determined individual and group tapu and mana.

Iwi and hapu members, bilaterally descended from a founding ancestor, owned discrete territory, but the hapu determined land use. Individuals' bilateral descent allowed them to affiliate with more than one hapu if they desired. A household officially affiliated with a hapu by means of genealogical link and participation in daily life of the group. Members could leave an overgrown hapu and start another one led by their chief's sons or brothers.

In a culture where true money did not exist and goods and services were compensated through gift giving, a man of high status who provided food and gift items during times of feasting (*hakari*) would greatly enhance his mana even though he and his family might have few possessions left to them afterward. Craftsmen were descended from chiefly lines in traditional society; each paid homage to the god of his occupation and was initiated through a series of rituals into his craft. Tattoo artists, raft and canoe builders, house builders, and carvers all were classified as *tohunga*, a title that conveyed the qualities of sacredness associated with "priest." *Rangatira*, or chiefs of the hapu, were often trained priests. They

were beneath *ariki*, or chiefs of the most senior hapu and supreme chiefs of the iwi. Commoners (*tutua*) were beneath priests.

Tohanga communicated with a pantheon of gods and repeated rituals associated with offering. They also maintained history, genealogy, stories, and songs by committing them to memory in the absence of written language. In this way, *tohanga* defined ancestral and family ties and each person's place in the tribe.

A memorial to ancestors was the or ancestral meetinghouse (*whare hui*), the center of community life. The *marae* was an open assembly space of sacred ground in front of it. When someone died, the body would lie in state on the marae for days. Farewell speeches full of mythological allusions and figures of speech could be heard along with high-pitched wailing by women. Then the body was wrapped in mats and placed in a cave or tree. The body was removed 1 or 2 years later so that bones could be cleaned, painted, and carried between villages for a second time of mourning before final burial in a sacred place.

Visitors to the marae brought with them memories of their dead. Māori saw themselves not as individuals but as part of the collective knowledge and experience of ancestors. An elaborate ritual in Māori language awaited visitors. Women called out a greeting that could include a ceremonial challenge. After a visitor replied, welcoming speeches were given, followed by song. Once ancestors had been praised and lineages established, the tapu of visitors was lifted. Hosts and visitors could exchange handshakes and pressing of noses (*hangi*). Before leaving, visitors made farewell speeches in the form of thanks and prayer.

Any business not completed on the marae before nightfall was continued inside the meetinghouse, a structure commemorating a well-known ancestor. The ridgepole inside symbolized his backbone, and the rafters symbolized his ribs. Carved posts on walls represented gods, legendary figures, cultural heroes, and other famous ancestors. Many new maraes today invite city-born children to learn Māori language and culture and to test their ideas against the wisdom of their elders. Voluntary associations and benevolent societies also enable Māori urban dwellers to maintain a distinct culture and identity as they champion their rights.

**MĀORI**

The Māori are a people of Polynesian stock who were the first human inhabitants of the islands of New Zealand. They arrived in double-hulled seafaring canoes. As a matter of custom and personal pride, Māori can recite their genealogy back to the ancestors who came in canoes. However, the custom, like many other Māori customs, is declining as many Māori have committed their genealogies to writing.

The Māori language is a Polynesian one that is part of the Austronesian group of languages. Māori is a part of the Tahitic branch but is also closely related to the Polynesian spoken on the Society and Cook islands.

Most Māori spoke their native language until after World War II. Māori was used both orally and in some New Zealand newspapers and literature. Today the language is in decline, and most Māori speak English, although there are attempts to preserve the Māori tongue. The disappearance of the Māori language is the result of Māori entering the mainstream of New Zealand life. It is estimated that only 20% of Māori now use the language in their homes.

Recent population estimates are that the Māori now number 250,000, which is roughly 9% of the

population of New Zealand. Moreover, white intermarriages with the Māori have occurred frequently, so there is now a considerable population of mixed Māori and European people. These are usually counted in the Māori population.

Most Māori are tall, brown-eyed, and wavy-haired with broad faces. They practice tattooing, an ancient art form called *ta moko* in Māori. The practice is based on an ancient myth about love.

Pre-European Māori were organized into tribes (*iwi*), subtribes (*hapu*), and small groups (*wanau*). They gathered food by hunting, fishing, and farming. They lived in small isolated villages. Woodcarving was used to decorate community houses, canoes, and other possessions. Pre-European Māori culture was oral and complex. Large gatherings were held at social centers to celebrate various rites of passage such as weddings and funerals. Food at gatherings would include fermented crayfish, and the gatherings featured dances called action songs.

Classic Māori religion involved myths, spirits, and taboos. The taboos forbid contact with certain people, places, or things. A violation of a taboo was a *hara* that could invoke the wrath of the gods. A *noa* was a kind of blessing that could lift a taboo.

MARETT, ROBERT RANULPH
(1866–1943)

The English philosopher and anthropologist, Robert Ranulph Marett was known for his philosophical analysis concerning the evolution of religious beliefs and rites. Born in Jersey, Channel Islands, Marett was a product of a traditional English educational system that stressed the basic classics common during the latter half of the 19th century. Marett pursued scholastic endeavors at both Victoria College and Balliol College. After completion of his education, he held several positions at Oxford University, including fellow and rector. Besides his academic pursuits, he was cofounder of the Oxford University Anthropological Society. The influence of classical thought with a philosophical perspective can be seen in his views

on both anthropology and religion. These influential views are apparent in his major published works of *Anthropology* (1912); *Faith, Hope, and Charity in Primitive Religion* (1932); and *Head, Heart, and Hands in Human Evolution* (1935).

Contributions and Perspectives

Marett recognized the critical importance of Darwin in the discipline of anthropology. For Marett, Darwinian evolution was the essential theoretical or philosophical framework by which the scientific study of our species becomes possible. Although he did not assign philosophy under the domain of anthropology, Marett had acknowledged that philosophy is the thread by which science operates. In this manner, both critical thought and open scope of inquiry can lead to greater scientific explanations. The philosophical inquiry reduces the rigidity and dogmatic acceptance of unquestioned theoretical explanations, especially when it is applied within an historical perspective.

Marett's perspective on the scope of anthropology would be conducive with most modern perspectives on this topic. Condoning a holistic view, the anthropologist should be well versed in anatomy, geography, linguistics, and the adaptations that the arrays of culture have provided. Although rudimentary, the acknowledgment of variations in phenotypic expressions is by no means an indication of worth; the common psychological operations of our species can express its humanity within the domain of culture. In this process, the anthropologist can understand the uniting factors of both political and religious structures found throughout the world. Thus, the anthropologist can indirectly augment the practical art of "healing" the political and religious fracturing within the world. This inevitably would require that the anthropologist understand both his or her own deepest self and the society that is the object of study. This places the anthropologist beyond the constraints of ethnocentrism inherited in Western philosophical thought and proceeds into the realm of humanism.

One of the greatest contributions made by Marett concerned his unique perspective on magic and religion. With his philosophical perspective and developments in psychology, Marett's views on religion were contrary to the established and influential perspectives presented by James Frazer and Burnett Tylor. For Marett, these views on religion became too restrictive and intellectualized to accurately depict all of the

processes involved in religion. The basis of the religion can be found in the subject awe of the individual toward the unknown or mysterious, a supernatural perspective prodded by both intellectual limitation and feelings. This primitive foundation of religion, aptly termed *animatism*, does not indicate a dualistic physical–spiritual existence. Rather, it should be seen in terms of powers constituted within or related to an object, all of which might not be associated with spirits. In this manner, there is a differentiation between the object and its power. Examples of these powers can be seen in the practice of witchcraft and the protective powers of objects or symbols, all of which do not constitute a spirit. Such a mysterious force gives religion a wider base than Tylor's animism.

The same consideration afforded to the basis of religion was also extended to the concepts of magic. In the evolution of religion, the process of performing magic (e.g., spell) is depicted as an extension of the emotional release of stress. Psychologically, for the individual, the process of transference stems from the will for action toward a particular end, although there may be a distinction between the object or symbol and the "reality" for the willed outcome. This process easily develops into prayer. The fluid motion from magic to prayer dwells in mystery of supernaturalism. When infused into social structures, the independence of magic can be seen in the concept of taboos. These unseen forces are unleashed to unknown destructive ends. Although there is a difference between taboo and witchcraft, the concept of magic as a supernatural force remains. Even when developed into prayer, the request for aid involves a perceived magical outcome steeped in awe. This process returns to Marett's view on animatism.

As a social anthropologist, Marett valued social psychology in the process of comparing religions of various cultures. Not totally discounting the individual, it is society that is responsible for the emotive tone of religion and its associated value system. This social reinforcement of values can be seen not only in taboos but also in regard to moral development of the individual. In the social arena, the individual's will and complete psychological constituents both are directed toward its rites of passage. In this manner, both magic and social development are blended to fulfill or complete the individual's maturity with freedom and enlightenment. Authority, both social and religious, relies on these psychological factors, essentially promoting faith and hope as a communal experience.

Although Marett's critique of Frazer and Tylor are perhaps well founded, the advancements made in the fields of both biology and psychology would question Marett's conclusions. These advancements, along with new philosophical perspectives, would certainly call for a reanalysis of his theoretical framework. Despite our scientific advancements, Marett's contribution cannot be diminished. His philosophical inquiry and differing perspective on psychology yielded a differing opinion on the fundamental principles governing primitive religion. Recognizing that feelings play an important role in human activity, the overrationalization of belief structures can be seen as seriously flawed. At the risk of misrepresenting Marett's intentions, it is possible that both the ambiguity of language in regard to religious categorization and "fuzzy" logic associated with emotion are partly to blame for the "pro" rational view. Considering the extensive influence of Aristotelian philosophy in Western thought, both Frazer and Tylor's views are understandable. However, Marett's unique perspective and cultural relativism bring deeper meaning to the evaluation of the human experience. The individual is more than an automaton, that is, a logic machine with incredible associative abilities. Marett's view of the human, as with anthropology, was holistic and complete, providing a deeper meaning for both.

MARMOSETS

Marmosets are the smallest platyrrhines or New World monkeys (NWMs). They are closely related to Goeldi's monkeys, tamarins, and lion tamarins, which together form the subfamily Callithrichinae. Marmosets reside in tropical rain forests in the Amazonian regions of Brazil, Bolivia, Colombia, Ecuador, and Peru. They are a flamboyant group of monkeys, with many species boasting fine-textured, multicolored pelage and adorning manes, moustaches, tufts, fringes, and crests. Unlike some NWMs, marmosets do not have prehensile tails. However, like the tamarins and lion tamarins, marmosets are characterized by the development of claw-like nails (tegulae) located on all digits except the hallux (big toe), the loss of one set of molars, and the regular production of twin offspring.

Three genera of marmosets have been classified: *Callithrix*, *Cebuella*, and *Mico*. Some taxonomists also include *Callimico* in the marmoset group. *Callithrix* are found in the Atlantic coastal regions of Brazil, whereas *Cebuella* and *Mico* are found in the Amazon basin of Brazil and a few surrounding countries. *Callimico* are found in Brazil, Bolivia, Peru, and Colombia. Marmosets, excluding *Callimico*, range in size from 126 to 450 g, with body lengths between 136 and 231 mm.

Cebuella is composed of one species: the pygmy marmoset (*C. pygmaea*). Pygmy marmosets are the smallest of the NWMs, with an average body weight of 100 g. They generally live in groups consisting of one adult male, one adult female, and offspring.

There is also only one species in the genus *Callimico*: Goeldi's monkey (*C. goeldii*). Goeldi's monkeys differ from marmosets in that they are slightly larger (400–535 g, 216–232 mm), retain their third molars, and give birth to singletons. This may mean that Goeldi's monkeys are more ancestral than other marmosets. Many people still debate whether or not *Callimico* should be placed with the marmosets or be considered a close but separate relative.

Marmosets are diurnal, arboreal, and quadrupedal. They are omnivorous, feeding on exudates (gum and sap), fruits, and insects. Marmosets are distinguished from the closely related tamarins and other NWMs by having large, chisel-like incisors that they use to gouge out holes in tree trunks to stimulate the flow of exudates. Their claw-like nails help them to cling to trees while feeding.

Marmosets live in communal social groups that have variable social organizations. Some live as monogamous pairs, whereas others live in multiple-female and/or multiple-male groups that are composed of extended family members. Marmosets are most often found in groups consisting of one breeding adult female, other adult females, several adult males, and offspring. Females become sexually mature at around 18 months of age. All group members play an active role in helping to raise the dominant female's twin offspring, carrying the young so that the mother can forage unimpeded. Marmosets have a life expectancy of 12 to 18 years in the wild.

At least 2 of the 14 species of marmoset are considered to be endangered: the buffy tufted-eared marmoset and the buffy-headed marmoset. The cause of the decrease in these populations is deforestation of these species' already small habitats.

MARQUESAS

The Marquesas, high-rise volcanic islands with jagged peaks and razor-edge ridges, are 740 miles northeast of Tahiti in French Polynesia. Experts believe that Marquesans may have come to their archipelago from Samoa more than 2,000 years ago. The islands lack coastal plains and coral reefs; the number of good anchorages is limited. Warring tribes lived in narrow valleys and sometimes cannibalized their enemies. Today 10,000 islanders, few of them full-blooded Marquesans, raise copra, taro, breadfruit, coffee, and vanilla beans watered by mountain streams.

The largest and most populated island is Hiva Oa, the burial place of French artist Paul Gauguin. Other islands in the southeastern group are Fatu Hiva, Tahuata, and two uninhabited islands, Motane and Fatu Huku, where Captain James Cook visited in 1774. Spanish explorer Alvaro de Mendana de Neira sighted the islands in 1595 and named them for his patron, Marquesa de Mendoza.

The northwestern group of islands consists of Ua Pu, Ua Huka, Eiao, Hatutu, and Nuku Hiva, which inspired Herman Melville to write *Typee*. In 1791, American sea captain Joseph Ingraham sighted the group and named them the Washington Islands. There is no truly urban center in either group today.

During the 18th century, the 100,000 Marquesans had a Neolithic technology based on stone, bone, and shell—clubs with flared semicircular upper ends carved with faces and geometric designs, ancestral tiki, and spears. Accomplished fishermen and sailors, they had the most extensive tattooing in all of Polynesia and raised pigs, dogs, chickens, tubers, and tree fruits from Southeast Asia and sweet potatoes from South America.

When Gauguin arrived in 1901, he found only 1,500 Marquesans left. Contact with Europeans and internal feuding had reduced the population. During

the early 19th century, the whalers who came to trade feathers and whale teeth for sandalwood and sweet potatoes also introduced new diseases. In addition, after France took possession of the Marquesas in 1842, many islanders were taken to South America as indentured laborers.

The Marquesas remain an overseas territory of France and have had internal autonomy since 1984. Public officials control resources, and patronage characterizes regional politics. France controls defense, foreign affairs, nationality and immigration, justice, higher education and research, communication, and currency; islanders send representatives to Paris. Marquesans, whose imports far exceed exports of fruit and flowers, depend on French social programs and military spending. Health care and education are free, and there is a 98% literacy rate. Most Marquesans are proud of their connection with French culture, but some want to return to traditional ways. The French outlawed many traditions and initiated a system of individual land ownership and equal inheritance; people became Catholics and assumed gender roles with men as breadwinners.

Islanders speak both French and Tahitian, the dominant Polynesian language. Older people continue to speak Marquesan, a language similar to Samoan. All maternal and paternal relatives are considered to be kin; use rights to land and mutual aid come from bilateral kin groups. Polynesian social hierarchies no longer exist, but islanders continue to keep genealogies. Reciprocity, generosity, and hospitality are valued. Display of imported goods—autos, appliances, and clothing—is evidence of class structure. Higher status jobs are held by European Polynesians or Polynesian Chinese with university degrees, whereas lower status clerical and public works jobs are held by Polynesians.

MARRIAGE

From the Latin *marito*, “to marry,” marriage is the social institution making the sexual union of two heterosexuals (and recently in some societies, also of two homosexuals) official, accompanied by an (often religious) ritual. It is one of the most important areas of study in social anthropology, since it is a social event as widely spread across the globe (despite the objections made as to its universality because of its multiple juridical, economic, ethical, and ritual implications) as it is exceptionally important for each society in particular. Because of this, societies, and especially those defined as “hot” by Claude Lévi-Strauss in *La Pensée Sauvage* (1962), that is, those characterized by continuous change, have instituted the registry of the event.

The aim of marriage is to have legitimate offspring who have the right to bear their ancestors’ name and inherit their wealth. By analogy, the biological, material, and symbolic reproduction and perpetuation of the *family* (i.e., the group of relatives, with the married couple and their married and/or unmarried children, etc., at its base, with which they cohabit, work, and share goods) and of the *lineage* (i.e., the wider group of individuals beyond the family who are interconnected through consanguineal kinship either patrilineally or matrilineally and who acknowledge a common ancestor) are achieved through marriage. By extension, the biological, material, and symbolic reproduction and perpetuation of the *ethnic group* (i.e., the group of individuals belonging to the same culture and acknowledging themselves as such) and of the *tribe* (i.e., a group that owns a territory and is homogeneous and autonomous from a political and social viewpoint) are also achieved through marriage. As a consequence, unmarried individuals and childless couples are marginalized and of low social esteem.

Marriage develops a dense network of rights and duties, starting from the spouses and the members of their close family (parents/children) and extending as well to those of their extended family (husband’s or wife’s parents and siblings, wife’s or husband’s parents and siblings) as to their lineages; in some cases, it even extends to the states they originate from. Its aims range from any sort of benefit and strengthening to the resolution of enmities, as can be seen in the following Greek cases: reconciliation of lineages engaged in vendettas in Anogeia in Crete

or belonging to opposed political parties after the civil war (1945–1949) in the village of Didima in the Peloponnese.

Processes

Despite marriage being primarily about sexual intercourse and resting on sexual attraction, love is seldom the sole criterion for choosing one's spouse. Most often, marriage is the result of an agreement between the two interested parties (arranged marriage), an agreement reached by the said parties after employing *strategies* (in this case, *matrimonial strategies*). These are, according to Pierre Bourdieu, activities repeated in time and aimed at satisfying the material and symbolic interests of families and lineages and, by extension, the interests of the entirety of the local community in a system of determined economic and social convictions. Even the case of marriage because of love is often the result of such a strategy, as ascending relatives from both sides of the intended couple consider the marriage to be in their interest and often arrange favorable conditions to promote sexual attraction between the said individuals that will, of course, conclude in marriage.

Apart from arranged marriage, the other process through which a couple can be driven to marriage is the abduction of the woman. According to common perception, the perpetrator of this act is always the man, although it is performed with the woman's consent in most cases. It is worthy of note that abducting one's wife-to-be is considered a sign of virility. The main reason usually brought forth for the abduction is disapproval of the choice of spouse on the part of the ascending relatives. However, it appears that other reasons, usually connected to *marital prestations*, can drive to this choice (see below).

Marital Prestations

Marital prestations, that is, provision of services and movable and immovable goods by one of the spouses (or their family) to the other spouse (or their family), are within the aforementioned rights and duties and an integral element of marriage in most societies. The most common instances of marital prestation are the *dowry* and the *bride price* or *bridewealth*.

The dowry, that is, the goods offered to the bride by her family (and which, directly or not, are offered to the groom and possibly his family), is encountered

in Europe and the Near East. It may consist of one or more houses, farms, servants, animals, jewelry, money, and the bride's trousseau (house equipment such as furniture, cookware, and mainly textiles as well as clothing for both herself and her husband). For instance, in modern Greece, the dowry represents an unofficial but particularly powerful customary institution that was even included in the Civil Code in 1946 and stood until 1983. When the female members of the family acquire the dowry, they waive the right to inherit the family's wealth, a right reserved to its male members. After 1983, the dowry is replaced by a *parental prestation* toward the daughter.

The bride price/bridewealth consists of services, money, or other movable and immovable goods given, as opposed to the dowry, to the bride's father (and occasionally her mother as well) by the groom. This custom stands mainly for societies outside Europe and the Near East. However, it is known that it equally took place in central and northern Greece until about 1950.

Still, there are cases where the marital prestation in place (dowry or bride price/bridewealth) is not given, such as when a woman is abducted. In some societies where the custom of the dowry is present, it is therefore not uncommon for a girl to be abducted with the covert agreement of her relatives; this allows the marriage to take place without them giving any dowry, as an abducted girl loses her right to dowry. Elsewhere, in societies where the custom of the bride price stands, a poor man might abduct his intended wife; in this case, he is relieved of having to pay for her.

Although these two kinds of marital prestation (dowry and bride price/bridewealth) are obviously contradictory and the existence of one appears to exclude the other, this is not necessarily always the case; they can sometimes coexist. Usually, though, if the prevalent custom is the dowry, the value of the bride price/bridewealth ranges from small to entirely symbolic. If the bride price/bridewealth prevails, then the dowry is of little value (usually limited to the trousseau).

Another form of marital prestation is the *premarital donation* (of money or other goods of value) offered by widows wishing to marry again to their next spouse, who has not been previously married. The same tactic can be used toward intended spouses by less wanted individuals, who are, for example, divorced, of old age, bad health, or reputation.

Marital prestations have been explained either in economic terms or in the light of considerations of

reciprocation and exchange. At any rate, however, their analysis and interpretation has clarified several points pertaining to the study of marriage.

Rules

Marriage is regulated by rules, among which one of great and global importance is the interdiction of incest, that is, of marriage between relatives. Each society has different conceptions as to who is a relative, with a view of preventing incest. The stringency of the rule forbidding incest thus varies from the interdiction of marriage between parents and children as well as between brothers and sisters, to the interdiction of marriage if even a single common ancestor is discovered. Some cases of marriage taking place between relatives are known, but these are exceptionally rare and connected with the devolution of authority (e.g., within royal families or the pharaohs in Egypt—Cleopatra originated from such a marriage). In general, societies stand in awe before the case of such a sexual intercourse, as can be seen in examples from mythology and literature (e.g., Oedipus and his mother), history (e.g., Alexander Borgia and his daughter Lucretia, Lucretia and her brother Cesar), and popular literature (fairy tales, ballads) that corroborate this finding. Despite this, in certain cases that border on incest, society (and the Christian Church) appears tolerant in order to avoid illicit cohabitation and especially the birth of illegitimate offspring.

In some societies the rule of *isogamy* or *homogamy* is particularly powerful; according to this, the spouses

must be of equal social, financial, intellectual, and so on status. If, on the other hand, the spouses originate from different social, financial, intellectual, and so on environments, this is a case of heterogamy. In this case, there is *hypergamy* on the part of the lower status spouse and *hypogamy* on the part of the higher status spouse.

Other rules govern the postmarital residence of the couple. Its most common forms are the *patrilocal*, if taking place in the groom's father's house or community, and *virilocal*, if taking place in the groom's house. Their opposites are the *matrilocal*, where the newlywed couple settles in the bride's mother's house or community, and more specifically, the *uxorilocal* installation, where they inhabit the bride's house.

When the postmarital location is independent, it is termed *neolocal*. The *avunculocal* installation, that is, when the couple settles in a spouse's uncle on the mother's side (e.g., in the Trobriands in Melanesia), is rarer. Still, there are cases where the postmarital residence is *bilocal*, that is, the couple chooses which spouse's relatives to live with, or even *ambilocal*, in case of alternate residence in both.

The locality of postmarital residence is directly connected to the systems of kinship. Usually, patrilocality goes together with patrilineal descent and matrilocality goes together with matrilineal descent. However, there are cases where this does not happen. For example, in the Congo, the husband lives in the same village as his father and sons but inherits goods from his matrilineal descent group. In general, the place of postmarital residence is more inconstant and complex in matrilineal populations, such as the Bemba in Zambia, where the husbands abandon the matrilocal group of their father-in-law after having served him for many years. Patrilineal populations are not entirely exempt from the aforementioned inconstancy and complexity either. The residence of the husband in his wife's homestead, when she belongs in a family with no male children, is such a case present in Balkan patrilineal societies (where patrilocality is the rule). The husband then takes the place of an adopted son, assuming the duties (work and care) toward his in-laws as well as the benefits (e.g., inheritance of their wealth, in addition to his wife's dowry) that come with this place.

The rule of *polygamy*, that is, the existence of more than one legitimate spouse at a time, applies in some

societies. *Polygyny*, the simultaneous occurrence of several legitimate wives, is the most common form of polygamy and is present in most Islamic countries (up to four wives), in China of the imperial era, in some African and Oceanian tribes, among others. *Polyandry*, when a woman has more than one husband (for example, in the Toda in India and some groups in Tibet), is rarer because of the inherent uncertainty as to the children's paternity. Therefore, *fraternal polyandry* is the most common form of polyandry, where a woman's husbands must all be brothers. It is thus at least known which lineage the children originate from. An extreme case of polygamy is *group marriage*, that is, simultaneous intercourse of several men and women, which has been the subject of much discussion in the past; however, this theory never achieved widespread acceptance.

The rule of *monogamy*, that is, marriage to a single man or woman at a time, applies in "cold" as well as "hot" societies and tends to become predominant. As long as this is in place, the spouses are prohibited from incurring another marriage.

The rules of *endogamy-exogamy* are related to the above rules (interdiction of incest, isogamy-heterogamy, postmarital installation, and monogamy-polygamy). In endogamy, the spouse is selected from within the same group (kindred, ethnotic, religious, etc.). Exogamy occurs in the opposite case.

Procreation

As the main aim of marriage is to have (legitimate) offspring, that is, to create a family, a good state of fitness of the individuals to be married is an essential requirement, because it guarantees the viability of the family through the ability to work as much its ability to reproduce through children. The latter is also related to the couple beginning their common sexual life before marriage in some areas (e.g., in areas of France, Corsica, and Greece) in order to prove a woman's fertility. However, in most societies, a woman's virginity is yet another requirement for marriage, and its demonstration during the first night of marriage is widely celebrated.

The inability to have offspring, a condition blamed on the woman, according to popular belief, can lead to several practices. These include social practices, such as breaking up of the marriage and taking a second wife or taking a second wife and keeping the first one in the same house (a type of *polygyny*, as happened, for example, in Mani in Greece). Another social practice is adoption, sometimes of a child chosen from one of the spouses' kindred group (an act with a clear sentimental motive, as children relatives are closer to natural children). In the village Didima, in Greece, the bond between the parents and the child can be further strengthened by marrying the child to a relative of the other spouse. In addition to the aforementioned sentimental dimensions, the above is also a strategy aimed at keeping wealth within a lineage. Nonsocial practices range from taking herbs and other homemade remedies, to, in modern societies, resorting to medical treatment or in vitro fertilization in order to have children.

Dissolution

In monogamic societies, the undoing of a marriage can occur by a legal process, the *divorce*, which does not, however, relieve the spouses of all the rights and duties contracted in their previous marriage. In general, the divorce appears to be an acceptable practice in Western societies, while in others, even when it is present, it receives a particularly skeptical treatment.

The death of one of the spouses does not end the rights and duties deriving from marriage; however,

in monogamic societies, it allows another marriage to take place. This is often almost mandatory, either because there are children (who must be raised by two parents) or, when there are no children, in order to have some. Particular forms of *secondary marriage*, as this type of marriage is termed with regard to the first (*primary*), are the *levirate* and the *sororate*. In some societies the second wife must be a sister of the first (sororate), while in others the second husband must be a brother of the first (levirate). An even more peculiar form of marriage subsists in the Nuer of Sudan, where, when a man dies without leaving any children behind, one of his younger brothers will marry a woman who will be considered the wife of the dead man. The children born through this *ghost marriage* are considered to be the dead man's children.

before Karl was born, his successful lawyer father had converted to Protestantism. His mother, born Henrietta Pressburg, took care of the household. From 1830 to 1835, Marx attended high school in Trier. At 17 years of age, he matriculated at the Faculty of Law of the University of Bonn, but he also attended courses in the humanities.

During his year in Bonn, Marx was a heavy drinker, fought a duel, and wrote poetry for Jenny von Westphalen, whom he married in 1843. She was the daughter of Baron von Westphalen, a city counselor in Trier. In 1836, Marx's father sent him to the University of Berlin, where Romanticism was less dominant than in Bonn. There he studied law as well as philosophy. He came into contact with Georg Hegel's philosophy and joined the left-wing Hegelian society, the Doctor Club, which was led by the theologian Bruno Bauer. Because it was supposed to be easier to receive a doctorate from the University of Jena at that time, he submitted his thesis, which dealt with the natural philosophies of Democritus and Epicurus, and was awarded his degree in 1841. In January 1842, he began writing for the newly founded liberal democratic newspaper *Rheinische Zeitung*. Because the newspaper was suppressed in 1843, Marx decided to move to Paris, where he began to coedit the *Deutsch-Franzoesischen Jahrbuecher* together with the liberal Hegelian Arnold Ruge. Only one issue of the yearbooks was published, but through its publication Marx got to know Friedrich Engels, who contributed to the work. Engels became one of Marx's closest friends throughout his lifetime. Together with Engels, Marx wrote the book *Die heilige Familie* (1845), in which they attacked Bauer. In Paris, Marx also met the poet Heinrich Heine, the Russian anarchist Mikhail Bakunin, and the French socialist Pierre-Joseph Proudhon. After having to leave Paris due to subversive journalism, in 1845 he settled in Brussels, where he further developed his views and founded a network of German, English, and French socialists. In 1847, the London-based League of the Just, a working-class movement, was in need of a solid theoretical foundation and so approached Marx and Engels. Both joined the organization, which was then renamed the Communist League. Marx wrote the *Manifest der kommunistischen Partei* for the organization. As a consequence of his political activities, Marx had to leave Brussels. He then stayed in Paris and Cologne, where he became editor of the *Neue Rheinische Zeitung*, which was strongly in favor of the

democratic forces. However, after the conservatives became stronger in 1849, Marx was expelled from Germany. Then he went to London via Paris. After a few temporary lodgings, Marx and his family moved to Dean Street in Soho, where they lived until 1856. Those years were destined to be full of worries. Marx was constantly in need of money, three of his children died, and he fathered an illegitimate son with the family's German maid, Helena Demuth. Engels, who was well known as a womanizer, agreed to accept paternity and the child was sent to foster care. Marx's financial worries, at least, were caused by his inability to manage his income. He had sufficient income, although his sole regular source of income were the articles he wrote for the radical *New York Tribune*, in which he dealt with all aspects of contemporary politics. In 1856, Marx received a small legacy that enabled the family to rent a house just off Haverstock Hill. Gradually, his financial worries receded, but at the same time his health got worse (boils all over his body) and he tried to treat himself with medicines such as opium and arsenic. Nevertheless, he slowly but persistently worked at his various projects, and in 1867 the first part of his main work, *Das Kapital*, was published. The other two volumes were compiled and published by Engels after Marx's death. Originally, Marx had planned to compose an additional five volumes, but these were never even drafted. One of the reasons why Marx was not able to finish his works was that he was committed to the International Workingmen's Association (First International), which took up a lot of his time from 1864 onward. At the beginning of the 1870s, there was strong conflict within this organization between Engels and Marx, on the one hand, and between the anarchists Proudhon and Bakunin, on the other. From then on, Marx's energies declined, he withdrew from active politics, and he further dedicated himself to his family. Marx managed to live a fairly luxurious lifestyle because Engels, after selling the partnership in a firm he partly owned, decided to support him with a certain amount of money each year. Marx moved into a large house on Maitland Park Road and began gambling on the stock exchange. In 1873, he suffered a kind of stroke, and thereafter he also dedicated a lot of time to improving his health. During the last years of his life, Marx had to cope with some misfortunes. In 1881 his wife died, and in 1883 his daughter Jenny died. Marx died in 1883 while sitting in his armchair.

Social Theory and Materialism

“Just as religion does not create man but man creates religion, so the constitution does not create the people but the people the constitution.” This was Marx's main criticism of Hegel, who started his social analysis from the idea of the state, and with this critique Marx was also following Ludwig Feuerbach, but this is not all. Marx had always started his analyses from the individual humans, and the main basis for the decisions of humans, according to Marx, is the class to which they belong (by “class,” he was referring mainly to the economic sphere). “It is not the consciousness of men that determines their being but, on the contrary, their social being that determines their consciousness.” Engels at some stage admitted, “Marx and I are ourselves partly to blame for the fact that the younger people sometimes lay more stress on the economic side than is due to it.”

Marx also applied these insights to his conception of history. It needs to be stressed that Marx himself never used the expression “historical materialism” or

“dialectical materialism”; instead, he preferred to call it the “materialist conception of history.” That conception was based on the insight that, for an understanding of history, one must focus on the productive activity of humans: “History was the—mostly unconscious—creation of laboring men.” “Labor is a process in which both man and nature participate and in which man of his own accord starts, regulates, and controls the material reactions between himself and nature.” Marx referred to the movement necessary for establishing an appropriate relationship between humans and nature as “dialectic.” Humans and nature were the two extreme poles of the dialectical movement.

Because he regarded the material conditions of humans as central, Marx claimed that he was a materialist. His understanding of materialism was, however, not connected to a specific metaphysical or epistemological conception of the world. The most detailed account of his materialist conception of history can be found in *Die deutsche Ideologie*, which he wrote together with Engels, who made the perceptive remark, “Just as Darwin discovered the law of development of organic nature, so Marx discovered the law of development of human history.” In their letters, Marx and Engels regularly compared their hypotheses to those in the natural sciences, in particular Darwin’s theory of evolution.

“History is nothing but the activity of men in pursuit of their ends,” and the activities of humans are always related to the social group, or class, to which they belong. “The history of all hitherto existing societies is the history of class struggles.” Although Marx referred to several types of classes in various passages, his treatment was not systematic. In *Das Kapital*, he distinguished among wage laborers (proletariat), capitalists, and landowners, and it is this distinction of classes that can be found most often in Marx’s work. Concerning his times, he claimed in the *Kommunistischen Manifest* that “society as a whole is more and more splitting up into two great hostile camps, into two great classes directly facing each other: bourgeoisie and proletariat.” However, he also noted the “constantly growing number of the middle classes.” In addition, the extension of the various classes often was unclear, in particular concerning the group of landowning peasants and the intelligentsia. Another subclass that he mentioned was the lumpenproletariat, to which “thieves and criminals of all kinds” as well as “vagabonds, people without a hearth or a home” belong. What unites people within

a class is always their relationship to the prevailing mode of production.

Given the fact that each human individual always belongs to a specific social and therefore economic realm, Marx denied the possibility of any objective account of the world. Of course, this theory also applied to his own account. Nevertheless, Marx distinguished between ideologies that were related to idealist philosophies and an unjust distribution of power and materialist conceptions. If a philosophy concealed the social contradictions, it was supposed to be ideological. Therefore, he justified the superiority of his own philosophical outlook by reference to the quality that it lays open social contradictions. However, this distinction is far from unproblematic. In addition, it was not theory alone that was important for Marx: “Philosophers have only interpreted the world in various ways; the point is to change it.”

Marx believed that laborers in a capitalist society were alienated, and his goal was to free laborers from alienation. He referred to alienated labor as that which occurred when workers were unrelated to the product of their labor and, as such, were alienated from themselves. As a consequence of their labor, there was a strong distinction between the social lives and personal lives of workers, and the workers are alienated from other humans. A central cause of the alienation was the division of labor, and Marx hoped that in a future community it would be dissolved and, as a consequence, that all humans would “hunt in the morning, fish in the afternoon, rear cattle in the evening, and criticize after dinner.” He expected and wished for a rural community to replace the mass societies of isolated individuals living in big cities.

Marx was not a prophet who described in detail what the future would be like. Rather, he tried to put forward a utopian ideal in which those aspects he criticized concerning his contemporary society would be dissolved. Such a better social order could be brought about only by revolution, and a revolution could come about peacefully as well as by means of physical force but never via terror. Yet a revolution always presupposes a class consciousness that the proletariat, according to Marx, had not yet developed sufficiently. He expected that eventually the “class struggle necessarily leads to the dictatorship of the proletariat; that this dictatorship itself is only a transitional stage towards the abolition of all classes.”

Marxism, both as a political ideology and as a social theory, ultimately derives nearly entirely from the *Communist Manifesto*, a pamphlet of roughly 12,000 words in the German language published in February 1848. This pamphlet allegedly was authored jointly by Karl Marx and Friedrich Engels. It was prefaced by a short, untitled, and extremely misleading Introduction.

Whatever was going to become true in the long-term future as a consequence of this original publication of the *Communist Manifesto*, it was certainly not true that the specter of communism was haunting Europe in February 1848. Certainly, 1848 was to be a year of revolutions. In Austria, Clemens von Metternich had announced that he was sustaining “a rotten edifice.” King Frederick William IV of Prussia summoned Horwegh, the revolutionary poet, to salute “a worthy opponent” and a man of the future. Most observers also agreed with Marx that the coming revolutions would have a social cause and/or an economic cause.

And so they had. But it was not the cause that Marx had foreseen. Whereas he attributed the forthcoming revolutions to capitalism, it would be nearer to the truth to argue that they were caused rather by the lack of capitalism. Apart from Prussia, which had already begun to suffer the same new developments as were occurring in some European countries farther to the west, there were two countries that escaped serious revolutionary disturbances. These were the United Kingdom and Belgium, the two countries in which capitalist industrialization had gone the furthest.

Essentially, Marx was neither a philosopher nor a social scientist but rather a prophet. In his own famous later words, he proclaimed, “Philosophers have only given different *interpretations* of the world; the task is to change it.” The Marxist system began as a propagandist myth, although Marx himself later aspired to make a substantial contribution to both economics and social science. Every argument of the *Communist Manifesto* was designed to produce an effect—not to interpret the world but rather to change it. The document that the Introduction was actually introducing purported to be the manifesto of the Communist Party. No such party existed at that time, and one object of the manifesto was to call it into existence. Nor had “Communists of various nationalities assembled in London and sketched the following manifesto,” as was stated on the first page. It had been written by Marx alone, without the actual and immediate assistance of even its alleged coauthor Engels.

Nor was the specter of communism haunting all or any part of Europe at the time of that first publication of the *Communist Manifesto*. Its true purpose was rather to produce that specter and thereby to bring about a future period during which communism actually would haunt Europe and other continents as well.

It is remarkable, and should have been remarked far more often than it was, that both substantial and even increasing numbers of professing social scientists, even during the last quarter of the 20th century, still proclaimed their own attachment to the putative theories and methods of a 19th-century predecessor and that there was apparently only one particular predecessor able to inspire such widespread and continuing devotion—representing a sort of “cult of personality.”

This is a phenomenon that should make anyone seriously committed to inquiry both suspicious of and curious about Marxism. One discouraging but possibly instructive parallel is with the applied pseudoscience of psychoanalysis, where one hears first of the great divide between Freudians and Jungians and then of further faction fights among rival disciples of those two founders. In the social sciences, however, such party loyalty has been mainly, if not only, to one particular very un-Victorian Victorian sage, namely Marx.

Still more particular, and still more deserving of remark, is the fact that the devotion extended beyond the wide limits of one area of study. In this unique

case, all of the author's works on every subject, as well as his political policies, were treated by his followers with similar respect and taken to be similarly authoritative.

One needs to contrast the social sciences with the natural sciences and, above all, with the standard-setting paradigm science of physics. There, not even the greatest contributors attract this kind of posthumous partisan devotion. Their contributions are quietly added to the ever-expanding corpus of at least provisionally established truth, and their names in the still current literature and textbooks appear solely in stock descriptions of eponymous principles, laws, or effects. Even in biology, the enormous contribution of Darwin—work that Engels, in his address at Marx's graveside, dared to compare to that of Marx in social science—has not inspired loyalties of the same sort. Although at least the vast majority of biologists currently subscribe to the neo-Darwinian synthetic theory of evolution, no one now takes all of Darwin's works as unquestionably authoritative even in biology, much less in anything else. As for the incomparable Sir Isaac Newton, most of his writings have never been, and most likely never will be, published at all. They dealt not with physics but rather with religion and were so grossly heretical that they had to be suppressed by Newton's friends.

In their day, two of the most notorious adherents to this particular Marxist cult of personality were Gyorgy Lukács and C. Wright Mills. It was, of course, Lukács who once insisted that the validity of the supposedly distinctive method of Marx could, and should, survive the falsification of all the findings thereby yielded. Mills, calling himself "a plain Marxist" and commending, above all, the method of Marx, apparently was equally reluctant to judge by results. Mills, understandably unwilling or, more likely, unable to offer a clear account of what that putative method was, proceeded to list the 17 "most important propositions of classical Marxism." With one exception, all of these important propositions of classical Marxism were then dismissed as false, unclear, imprecise, misleading, unfruitful, careless, confused, or quite clearly wrong. Proposition 11, the sole exception to this absurdity of errors, was correctly put down as a tautological truism. So, at the end of the day, the plain Marxism of Mills was simply his invincibly stubborn commitment to what only a Greek could, without affectation, describe as Marxist *praxis*. He continued to avow his total solidarity with

"the new world" extending from China and the Soviet Union to Cuba.

The significance of such stubbornly blinkered commitments has been fully appreciated by several of the most well-girded critics of Marxism. Lewis Feuer, for instance, insisted that the Mosaic myth is "the invariable ingredient of all revolutionary ideologies" and then proceeded to point out similarities between the conversion experiences of both modern revolutionaries and more traditionally religious revolutionaries. Sydney Hook often argued, "Marxism today signifies an ideology in Marx's original sense of that term suggesting more of a religious than of a strictly scientific, rational outlook on society." As Hook well knew, the apocalyptic eschatology, the utopian historicism that has been of such decisive importance in winning converts to Marxism, was originally derived by what Marx was pleased to call a philosophical analysis, from the Hegelian secularization of a Christian philosophy of history. The lifelong atheism of the "founding fathers" (Marx and Engels) irrecoverably deprived such reassurances of their only sensible foundation—the promises of a provident Creator.

The second thing to emphasize is that there were, during the second half of the 20th century, many remarkable similarities between defensive expedients favored by contemporary Marxist intellectuals and the maneuvers performed by apologists for the Christian religion. One of the most ancient, as well as the most outrageous, was that summed up in the patristic slogan *Credo ut intelligam* [I believe in order that I may understand]. A sacred system is immunized against hostile criticism by insisting that the necessary prior understanding is vouchsafed only to the totally committed.

When Bertrand Russell returned from visiting the Soviet Union in 1921 to write *The Theory and Practice of Bolshevism*, he became perhaps the first to describe what was not yet labeled Marxism–Leninism as a new secular Islam. Since then, several critics have argued that what Marx and Engels, and their 20th-century followers, loved to call "scientific socialism" is a religious system rather than a scientific theory and that claims to be scientific are as baseless and abandoned, for the same propaganda reasons, as those of Christian science.

Having seen how Marxism started from a barrage of falsehoods and pretensions, it is well to see how Engels saw the achievement of Marx after his death. In the first part of his memorial address, Engels

asserted, “Just as Darwin discovered the law of development of organic nature, so Marx discovered the law of development of human history.” This part concluded with the claim, “Thus was this man of science.” In the second part, Engels spoke of Marx “as a revolutionary working tirelessly for the enrichment of the poor and the emancipation of the oppressed.”

In an often quoted rebuke to Thomas Malthus, Marx wrote, “A man who tries to *accommodate* science to a standpoint not derived from science itself, but from outside interests that are alien to science itself, such a man I call *gemein* [cheap].” It was, nevertheless, a charge of which Marx himself was systematically guilty in respect of what was, for him, the most fundamental issue.

Look first at *Das Kapital*, the magnum opus that was supposed to provide the long-promised scientific proof for the sweeping historical theses of the *Communist Manifesto*—proof for its “philosophy of history.” The most fundamental and crucial of these was the immiseration thesis. According to *Das Kapital*, “The accumulation of wealth at one pole . . . is at the same time, the accumulation of misery, the torment of labour, slavery, ignorance, and brutalisation at the other.” Faced with the decisive falsification of his crucial contention, Marx simply suppressed the data. Hence, in the first edition of *Das Kapital*, various available British statistics were given up to 1865 or 1866, but those for the movement of wages stopped at 1850. In the second edition, all of the other runs were brought up-to-date, but that of wage movements still stopped at 1850.

Suppose that we look at the *Correspondence*, never forgetting that this was subject to at least two systematic prunings before its eventual publication. The Marquis de Vauvenargues once noted that “for the philosopher, clarity is a matter of good faith.” This maxim is equally true for the social scientist. We call into evidence a letter to Engels dated August 15, 1857. The letter is especially notable inasmuch as it also reveals that Marx himself intended dialectics to be, as so many readers have found them to be, obfuscatory. Thus, he wrote, “I took the risk of prognosticating in this way as I was compelled to substitute for you as a correspondent at the *Tribune*. . . . It is possible I may be discredited. But in that case it will still be possible to pull through with the help of a bit of dialectics. It goes without saying that I phrased my forecasts in such a way that I would prove to be right also in the opposite.” So much for Marx the pseudoscientist.

There were Communist ideas and spokesmen for them long before the first publication of the *Communist Manifesto*. Among these spokesmen were John Lilburne and his Levellers, who generally opposed the “grandees” or officers in Cromwell’s Republican New Model Army during the first phase of the English Civil War during the 17th century. In the various revolutions of 1848, Marx and Engels both participated very actively, trying as hard as they could—and this was to a trifling extent—to make them Communist. All of the relevant writings of both Marx and Engels have been published under the name of Marx as *The Revolutions of 1848*. But the great event of the 19th century that was of most interest to Marx and Engels was the Paris Commune. This, however, was not a Communist revolution, although Marx was to draw many lessons from it. It was a patriotic revolt of the Commune of Paris intended more effectively to organize patriotic defense against the Prussian invaders.

It was not until the 20th century that a revolution led by a Communist Party first achieved state power. This was the Bolshevik Revolution of 1917, which transformed the former Russian Empire of the Tzars into the Soviet Union. Before World War I, there were several at least nominally Marxist Social Democratic parties on the continent of Europe (e.g., in Germany and Italy). But the illegal Russian Marxist Party, led by G. V. Plekhanov, at its 1905 conference split into two factions: the Bolsheviks (majority) and the Mensheviks (minority). It was the Bolshevik faction, led by V. I. Lenin, that later launched the October Revolution and thereby transformed the former Russian Empire into the now also former Soviet Union. Here it should perhaps be remarked that Plekhanov (who was respected as the founder of Russian Marxism) insisted, from 1905 until the end of his life, that there could not be a genuinely Marxist revolution in a country with a relatively tiny proletariat rather than the sort of advanced capitalist country that Marx himself had in mind.

The same is true of the other 20th-century revolution that, in terms of the size of the population involved, was a much greater revolution—that in China. There the relatively tiny Chinese proletariat was wiped out in the suppression of the Canton Commune, and the first Chinese Red Army was manned nearly entirely by peasants. The period of the dictatorship of Mao Zedong, which established a new world record for the number of people starved to

death in a famine (30 million), is now officially forgotten. Everything has changed since the day when the faction of the late Deng Xiaoping, called “the capitalist roaders” by their opponents, won power. That faction apparently still retains power now, years after his death. Anyone now wanting a statement of government internal policy is given a 13-page typescript copy of a conference speech he made on December 13, 1978. It remains only to remark that the capitalist roaders have achieved for China, over the past 10 years or so, by far the highest average economic growth rate anywhere in the world.

NEO-MARXISM

The Frankfurt School has become one of the mostly widely adopted forms of neo-Marxism. It grew out of the Institute of Social Research at the University of Frankfurt, Germany. It is sometimes referred to as *critical theory*, meaning a special kind of social philosophy. It gathered together people who were severe critics of capitalism but believed that Marxism had become too close to communism. They believed Karl Marx’s followers were supporting only a narrow selection of his ideas.

Neo-Marxists view class divisions under capitalism as more important than gender/sex divisions or issues of race and ethnicity. Neo-Marxism encompasses a group of beliefs that have in common rejection of economic or class determinism and a belief in at least the semiautonomy of the social sphere. They also claim

that most social science, history, and literary analysis works from within capitalist categories and say neo-Marxism is based on the total political-economic-cultural system.

During the Nazi regime, the members of the school fled first to Geneva, Switzerland, then to the United States. They became attached to the department of sociology at Columbia University in 1935. In 1941, they relocated to California. In 1949, some of them—Max Horkheimer, Theodor Adorno, and Friedrich Pollock—returned to Germany and 2 years later reestablished the Institute for Social Research. Horkheimer served as director and believed in a holistic approach, combining theory and practice.

The neo-Marxists, after seeing the failure of working-class revolutions in Western Europe after World War I, chose the parts of Marx’s thought that might clarify social conditions that were not present when Marx was alive. They filled in what they perceived to be omissions in Marxism with ideas from other schools of thought.

While in the United States, Horkheimer and Adorno had focused on the commercial media. They argued that the media willingly manipulate a passive and irrational public. They emphasized the great influence the media exerts on the thoughts and attitudes of society and the way in which it encourages people to think about their lives. Neo-Marxism first became an influence in the United States in the late 1960s and the early 1970s, through the work of Horkheimer and others.

MASKS, CEREMONIAL

A ceremonial mask is defined as a headdress or an object that covers the face for purposes of protection, ritual, entertainment, transformation, and disguise. Ceremonial masks have different characteristics and functions, depending on the culture that is associated with the particular mask. There are some areas in the world where masks are worn to communicate with ancestors, to ward off evil spirits, to entertain a

crowd through dramatic arts, or to express prestige and wealth.

The ceremonial masks of Africa vary throughout the continent. Masks continue to be of great importance within certain African societies. Art has a great influence over the masks that have been produced. Art is thought to be an expression of ancestral worship. The most prominent area where ceremonial masks are present is a location from within the center of the continent moving from west to east. African masks serve several purposes. Masks not only are representations of ancestors but also are used as a means of communication between the two groups of living and nonliving individuals.

Andreas Lommel, in *Masks: Their Meaning and Function* (1970), stated that there are four categories of African masks. The first category is composed of realistic masks that often represent beautiful women. These are located throughout western Africa and the Congo. The second category is made up of animal masks. They represent animals and are located in all areas. They date back to hunting societies. The third category is abstract masks. These are more apparent in Sudan, where desert nomads had great influence. The last category is of expressionistic style. Even though this type is seen as being universal, there is evidence that they are more prominent in the Congo and Cameroon. Masks were constructed from bronze, usually worn by a deceased king to preserve his face. Terra-cotta and wood were also materials used to construct masks. Wooden masks were used in ceremonies or rituals to honor the gods.

African masks vary in purpose. There are four main types of African masks: initiation, secret society, fertility, and festival masks. Initiation masks are very sacred and used during initiation rites. It may be forbidden to wear certain initiation masks, but they may be displayed during the ceremonies. Secret society masks hold special powers within the specific groups they represent. Only members of the specific

society a mask represents are able to see this mask, and it is destroyed after use. Fertility masks are used by men in relation to agriculture events. These masks contain special powers related to the rain and fertility. There are numerous festival masks used during any spiritual activities, including hunting and harvesting ceremonies.

Melanesian ceremonial masks are similar to those of Africa in that they are used by secret societies. The masks are used during religious or spiritual ceremonies and represent spiritual beings and ancestors. Some masks are associated with protection and are made to resemble skulls. According to Adrienne Kaeppler in *Ceremonial Mask: A Melanesian Art Style* (1953), during some ceremonies, not only are large extravagant masks worn, but also the bodies and faces of individuals are painted with “red burned clay, black with soot, and white with lime from burned shells or coral.” Ceremonies are performed to appease specific gods and to shield against tragedies such as illness and natural disasters. Melanesian masks are often referred to as being expressionistic due to the presentation and great amount of emotion expressed from the masks.

Ceremonial masks in Ceylon are associated with dramatic performance and traditional myth. Demons and evil spirits are believed to be the cause of illness. The Ceylonese believe that these evil spirits can cure a disease through performing an exorcism and other ceremonies. The mask is used to vanquish and cure

the disease once the disease is transformed into a physical form. These ceremonies allow evil spirits to transform into spirit helpers.

Tibetan masks reflect Indian influences and have shamanistic characteristics. Many masks represent supernatural beings and spirits that aid in decision making and deliver warnings. Some masks are used during midwinter or midsummer celebrations. Ceremonies involving the elimination of illness require dance and other performances of rites to neutralize the illness that is represented through the masks themselves. Tibetan masks see their origins stemming from the Buddhist tradition.

North American tribes have created two main types of ceremonial masks. The first is an animal-type mask that represents the connection between humans and their animal ancestors. The second type consists of masks that reflect spirit helpers. Shamanistic forms of masks are present in the northwest part of the continent. Many masks are highly artistically creative and are usually formulated with both human and animal features.

Wooden carved masks are common among the Iroquois. The masks are reincarnates of mythical creatures and deities. There are several types of masks used during different occasions. These include the motherhood mask, the mask of the adviser, the beggar mask, the mask of storm, and the scalp mask. Masks are used during ceremonies for successful harvests, hunting, and protection. Masks from the southwestern tribes have a unique appearance and are made from soft skin to symbolize male deities. The masks that do represent a deity can stay within a village for a period of time while he entertains through dance, provides gifts for children, and delivers punishment to deviant individuals. Masks represent hierarchy and are representations of gods. Native Americans located in the Plains use minimal masks and ceremonies such as the bear mask and buffalo dance. The focus of each ceremony in which the masks are used is on the object of desire such as the bear or buffalo.

Central America is well known for its death masks. Death masks were found buried with ancient mummies. Others were representations of different gods. Masks were made out of black- or greenish-colored stone found in Mexico and Teotihuacán. One of the most famous masks is called "Our Master the Tortured One." This mask totally engulfs the whole body of the Mexican god Xipe Totec. This particular

god is in connection with the spring and has the ability to renew all things.

Japanese masks are no longer a representation of religion. Instead, today they are genuinely works of art. Theater is the foremost driving force of these artistic masks. Japanese masks are some of the oldest masks found in the world. They are also known as *gigaku* and are accompanied with music and dance in a theatrical form. *Bugaku* plays came after the *gigaku* plays. The main difference between the two is that the *bugaku* no longer uses masks within the performance. *Nō* is known to be the most impressive Japanese masks. The five characteristics of the *Nō* masks represent gods, men, women, madmen, and demons.

Australia does not have any records of separately physical masks, but the Aborigines have used another technique. Instead, there has been traditional use of different paint and art that cover the face and body. The paint is arranged in specific patterns. The masking of the face and body uses the same ideology as does a physical mask. Many ritual ceremonies are performed to develop a connection with the ancestors and the Dreamtime. The Aborigines paint their faces and bodies during ceremonies and celebrations involving the transmission of knowledge and legend to their people.

Masks are seen all over the world. Many can be identified by the materials from which they are made and by the style and colors used. There is no common definition of a mask due to its multiple uses and forms. Masks serve the purpose of relating with those beings or forms of other worlds in rites of transformation and recalling historical events within the culture.

The relationship between a mask and the person who wears the mask is intimate. The person becomes a medium for the spirit or power that the mask represents. The person and mask work together to communicate a message or an action. In many societies, there is also a relationship between the artist who creates the mask and the mask itself. It is thought that the energy, attention, and detail paid to a mask during its creation generate a power or spiritual force within the mask from the moment it is completed. The artist or carver takes great pride in the production of the mask.

Different areas use various materials to construct their ceremonial masks. Some of these materials include the objects within the immediate environment such as bark, branches, shells, stones, pieces of leather or hide, clay, and animal parts. Other masks

may include human attributes such as hair, usually from a shaman or a powerful individual within the particular society.

The study of masks continues today. There is much to learn and uncover about the secret world of masks. Masks are hierarchical, religious, spiritual, and representations of the unknown. It is difficult for any one person to fully comprehend the importance of a mask used in past civilizations. Much of what is learned is still considered quite hypothetical and incomplete. Anthropologists have made their best attempts to try to understand these objects, their meanings, and their functions.

MATERIALISM, CULTURAL

Societies survive and successfully reproduce themselves only insofar as they meet the elementary material needs of a certain minimum of their members. This observation is the starting point for cultural materialism, a living theoretical tradition founded and defined by the American anthropologist Marvin Harris (1927–2001). Of cardinal importance, in Harris's view, is the fact that people pursue their needs in the context of intimate dependence on the natural environs for their energy requirements. It follows that we may expect the most important causes of the similarities and differences between societies to arise at the sites where humans maintain their most immediate commerce with the natural world. The realms of demography, technology, and economy best answer to this description. Of all sociocultural realms, these are also those most subject to law-like

regularities and therefore to scientific investigation. Harris draws the conclusion that if anthropology is ever to rescue itself from the siren calls of various fashionable idealisms, and if it is one day to reclaim itself as a science, then it will be to these “material” aspects of society and culture that it will turn.

Impressively wide ranging, in the hands of Harris and other adepts, cultural materialism has been able to offer empirically informed but connected theorizations concerning an apparently unlimited number of cultural processes and historical periods. The source of food taboos; the origins of egalitarianism in many band societies; causes of the variety of kinship systems; why the Oedipus complex is an expression of aggressive male competition; why beef has been central to U.S. meat consumption; the reasons for the demise of the U.S.S.R.; the role of Haitian peasant voodoo in resource circulation; the origins of the state, war, and capitalism—these and many other social scientific questions have been opened up anew under the confident cultural materialist pen. At the same time, the explanatory power of the theory has been tested against virtually any contending school of thought one cares to name. Needless to say, for its adherents it has not been found wanting in these encounters.

Although cultural materialists seem to have a rather embattled view of themselves, they are not so alone as all that. In fact, they float on a broad if turbulent intellectual stream within modern anthropology. The focus they put on evolutionary dynamics was a hallmark of anthropology's founding fathers and later of Leslie White (1900–1975). The tacit functionalism of cultural materialism was prefigured in the work of Bronislaw Malinowski (1884–1942), and the emphasis on scientificity by A. R. Radcliffe-Brown (1881–1955). Cultural materialism's stress on ecological influences had been taken a long way by Julian Steward (1902–1972), and a concern with history and material culture marked the work of Eleanor Burke Leacock (1922–1987). In the 1960s and 1970s, when Harris was writing programmatic works like *The Rise of Anthropological Theory* (1968) and *Cultural Materialism* (1979), Marxism was a significant force in Western academies. Broader still are the utilitarian, materialist, empiricist, and behaviorist currents that are component parts of much Western common sense, not to speak already of the great prestige of Darwinism. Cultural materialism conscientiously distinguishes itself from each of these trends and viewpoints, but would have been inconceivable without them.

At the heart of Harris's work, and of cultural materialism ever since, are two sets of ideas. The first set is methodological and encompasses an interest in developing a scientific approach to culture and society. This interest is pursued through an insistence on "operationalizing" all major concepts and through a preference for "etic" over "emic" explanations. The second set of ideas is substantive in nature. Humans and human societies being what they are, on the balance of probabilities the best explanations for any given sociocultural phenomenon will be "materialist" ones. The "material" invoked in this instance leads us to distinguish between the "infrastructural," the "structural," and the "superstructural" aspects of any social whole. Let us now turn to these elements.

Operationalism

Anthropology, according to cultural materialists, suffers from a surfeit of half-baked and ill-digested concepts. Kinship, society, culture, symbol, caste, and numerous other concepts tend to be used haphazardly and anointed with idiosyncratic meanings. This is partly because little effort has been put into generating intersubjectively agreed-upon definitions. It is also partly because most anthropologists are convinced that anthropology neither can nor should pretend to the kind of scientificity possible in the natural sciences. And finally it is partly because many anthropologists make it their primary concern to interpret those aspects of culture, such as cosmology, myth, and ritual, which are least susceptible to properly scientific investigation.

Such attitudes are too complacent by far for the cultural materialists. The undergrowth of mutually and often self-contradictory theories needs clearing away. For a start, each anthropologist should shoulder the responsibility of specifying the logical and empirical steps any given investigator would have to take to independently establish the existence of the entities and causal relations posited in their original theory. This is what it means to operationalize one's concepts. Doing so is, in principle, entirely possible for a social science like anthropology and should in any case be accepted as an ideal to strive for. Moreover, as a corollary of this ideal, anthropology should confine itself to investigating aspects of sociocultural life open to being reinvestigated and assessed by other anthropologists. It is fine for a Carlos Castaneda to regale us with stories of his apprenticeship to the Mexican

shaman Don Juan; it is entertaining to learn of their epic journeys to the far reaches of the mind; but it is not science, and consequently it is not anthropology.

Etic and Emic

Setting out to understand their fellow humans as objectively as possible, anthropologists encounter a difference between their own thoughts about those they study and the account of themselves given or presupposed by those they study. Typically, different kinds of causal relations and phenomena assume significance in each case. Linguistics, faced with analogous difficulties, developed a useful distinction. It distinguished between phonetics (the study of the different types of sounds generatable by the human vocal apparatus) and phonemics (the study of the sound discriminations that speakers of a particular language employ in making meaningful utterances). The two are not the same (as anyone first encountering the "inaudible" tonal distinctions utilized in some Asian languages will attest). By way of analogy, the linguist Kenneth Pike suggested that the difference between observer and observed in anthropology could be clarified by speaking of "etic" and "emic" orientations to the phenomena, respectively.

This is a distinction, of course, that exists for the anthropologist alone. On Harris's reading, an anthropologist who takes up an emic approach is one who makes native conceptions, whether conscious or unconscious, the standard against which to judge their own anthropological concepts. By contrast, an etic approach is not concerned with whether the explanations it produces would or could make sense to the people concerned. The only issue of moment for an etic approach is whether these explanations are scientifically valid, fruitful, and parsimonious. Insofar as we are interested in the real causes of sociocultural phenomena, and insofar as we do not intend to limit ourselves to ponderously reproducing a people's illusions about the reasons for their behavior, we must necessarily give pride of place to etic accounts.

Material Infrastructures

Where are the real causes of sociocultural phenomena likely to be found? By speaking of cultural *materialism*, Harris indicates his most general answer to this question. This is a materialism of the midrange. It is *epistemological* (natural, and many social entities

and relations exist independently of our thoughts about them), and most important it is *causal* (mental phenomena emerge from and are dependent on material phenomena, whereas the reverse is rarely the case). As for *philosophical* materialism (the contention that reality is ultimately composed of matter rather than ideas), for Harris the issue is a “sterile” one.

Darwinism and Marxism provide the main intellectual coordinates for this account of sociocultural causation. From Darwinism, cultural materialists derive an emphasis on humans as creatures who face a series of constraints to which they must adapt. Nature, on this view, is the realm par excellence of physical, chemical, and biological limits. These limits cannot be abolished on a whim. They can be modified, if at all, only at the cost of expenditure of energy. Sociocultural forms either instantiate ways of more or less optimally regulating the capture and expenditure of energy from nature so as to meet the fundamental biological and psychological needs of their members, or they cease to exist.

It is consequently in the areas where a sociocultural formation most directly abuts onto nature that we are entitled to search for the most likely determining influences on the remainder of that formation. This is an idea inspired by the Marxist conviction that the characteristic features of a social totality are derivative of its mode of production. Harris finesses this claim by etically differentiating three sociocultural domains. In the *infrastructural* domain, we find those technologically mediated human activities oriented to producing the means of subsistence and to ensuring biological reproduction. In the *structural* domain, we find the domestic and political organization of these activities and the conflicts arising therefrom. And in the *superstructural* domain, we find everything else: all behavioral events at a greater remove from subsistence concerns (rituals, games, music, science), as well as, in practice, most aspects of a people’s mental life (religion, myth, ideologies, philosophies).

Most important, unlike versions of Marxism that credit a single determining factor (perhaps class, perhaps the “economic base”), cultural materialism juggles with a suite of infrastructural variables. Demographic pressures, nutritional requirements, subsistence technologies, ecological changes—these and other factors may be appealed to depending on the nature of the case. On the other hand, cultural materialism distinguishes itself from sociobiology by an ambition to explain sociocultural differences as well as similarities. So rather than saddling itself with a set of would-be explanatory genetic and evolutionary universals, it appeals always to *this* particular land yield, *this* particular climatic pattern, *that* specific advantage of cows over pigs.

Cultural Materialist Ideals

Harris observes more than once that political commitments sometimes trump the commitment to objectivity within anthropology. In any quandary of this kind, he considers anthropologists to have a primary duty to the truth. Perhaps it is not surprising, therefore, that observers routinely fail to notice that for Harris, the mission to secure anthropology as a science has an ethicopolitical significance as well as a cognitive one. Typically, this emerges in the context of intellectual polemics. A good example is the debate over the significance of Aztec sacrifice.

In *Cannibals and Kings* (1977), Harris attempts to account, among much else, for the Aztec practice of sacrificing war captives, a theme also explored in cultural materialist vein by Michael Harner. The point stressed by Harris and Harner is that Aztec cannibalism was almost certainly unique. The functionaries of the Aztec state took what was probably a common practice in the Americas and not only made it the center of ecclesiastical life but also escalated it to unprecedented levels (estimates for the 15th century go as high as 250,000 people killed in some years). This, Harris and Harner contend, must be accounted for by population pressure, the uniquely depleted animal protein sources in the Mexican Valley, and the advantages to the Aztec ruling class in maintaining a "cannibal empire."

Reviewing Harris's book, Marshall Sahlins finds these ideas laughable. He challenges the cultural materialist claim that protein sources were minimal in the Mexican Valley and stresses the impossibility of accounting for the elaborate holy temple rites of the Aztecs on the basis of a simple need for meat. As Sahlins would later comment: "Why build a temple, when all you need is a butcher's block?"

Harris's rejoinder is noteworthy for its tone as much as its content. In his view, Sahlins is not only objectively wrong, but his account is little more than a much belated apology for Aztec ruling class ideology. Hostility to the cultural materialist's etic elucidation of why the priests at the main pyramid in Tenochtitlan and numerous other sites were *really* killing captives merely lends plausibility to Aztec religious mystifications.

Scientific objectivity, then, is for Harris our only reliable weapon against the disguises worn by exploitative social relations, wherever and whenever they might be. And exactly because it alone is capable of tearing off all ideological veils, science is the only possible panhuman way of knowing. Nothing else, as he writes in *Cultural Materialism*, can "transcend the prior belief systems of mutually antagonistic tribes, nations, classes, and ethnic and religious communities in order to arrive at knowledge that is equally probable for any rational human mind."

What jumps out from a statement like this is that it sounds very much like an *idealization*. Surely the *practice* of science is usually less elevated. Harris is happy to grant both points. Nonetheless, it is precisely as an ideal that science deserves to be defended.

Evidently, cultural materialism comes here to its symptomatic point of exception. Alone among all

social phenomena, science finally is to be exempted from etic explanation. Its truth, too valuable to be surrendered to materialist demystification, inheres in its ideal. This, speaking loosely, was Harris's emics, the account he rendered to himself of why etic explanations must be paramount.

Criticisms of Cultural Materialism

Cultural materialists shot argumentative arrows in many directions. Not a few have been shot back. For Jonathan Friedman, cultural materialism's causal explanations are merely redescrptions of empirical correlations. Were they to be taken seriously as explanations, they would in any case prove untenable. The unidirectional model of causation from infrastructure to structure and superstructure is not just a travesty of Marxism, it is theoretically implausible. It misses the relative autonomy of any social structure from its technoenvironmental conditions. Empirically, the theory fares no better, since cultural materialism can only account for the many instances of social change within the same technoenvironment, or of technological changes within the same social form, at the price of its own incoherence.

Maurice Bloch likewise attacks cultural materialism's point of pride: the fact that, unlike many "idealist" approaches in anthropology, it actually puts forward concrete explanations to account for specific historical changes and social functions. Bloch's observation is that these explanations are entirely ad hoc. If cows in India are holy and therefore ineligible to be eaten, Harris will look around for why etically this makes good economic sense. Were circumstances otherwise, and cows abhorred in India, Harris would doubtless discover equally meritorious reasons for why keeping cows out of India is economically rational. The explanation, then, is unfalsifiable but trivial. The only way to circumvent the problem would be to hazard a general theory as to the conditions under which cows anywhere will be considered holy; but this Harris does not do.

In the end, most anthropological criticisms of cultural materialism emerge from a common discomfort. This is the unshakable sense that, whatever the denials, for Harris and his cothinkers human cultures are finally not *real*. This is a criticism that cuts along both the substantive and the methodological axes of cultural materialism. The objections in each area might be summed up as follows.

Harris's "cultures" have a sort of emaciated reality, and his "superstructures" in particular are ontologically anemic ("mystifications"). It is as if the further you climb away from the ecological, demographic, economic, and technological determinants, the more insipid and less meritorious of sustained "scientific" consideration do the human phenomena become. The supposed gradient of causality is treated simultaneously as a gradient both of material quiddity and scientific credibility. But nothing else is to be expected if the necessary requirement that a culture adapt to its environment is made to stand in for the entirety of its inner logic.

Kindred objections emerge on the methodological front. Operationalizing one's concepts is not the same thing as subjecting them to critical interrogation. And attempting to ensure that one has an "etic" approach to phenomena will not cleanse one's concepts of the ontological commitments they inherit from their mother culture. To make this point is not, as Harris supposes, to elide the differences between nonscientific and scientific knowledge. It is not to suggest that we can neglect to carefully distinguish between thought and behavior, theory and practice, or subjectively and objectively verifiable statements. Nor is it to promote the simple-minded claim that anthropology's etic science is little more than the imposition of one particular emic universe on another. But such an imposition is exactly what anthropology threatens to become when it neglects to critically reflect on its scientific practice as a sociohistorical and cultural practice.

MATRIARCHY

Matriarchy is a term we use with two main meanings: (1) domination by female members of society and (2) women-centeredness in society (such as in descent, place of residence, economy, politics, religion, family). Scholars who use the term in the second sense stress that the concept of matriarchy does not parallel the concept of patriarchy (domination by male members of a society) insofar as the patriarchal domination structure does not exist in a matriarchal society.

In the 19th century, matriarchy or "mother-right" was thought to be representative of an early and primitive stage of social evolution. This stage was overcome by the "higher" stage of the "male principle." The idea of matriarchal prehistory, however, has not only been used to justify patriarchy but also to overthrow it. In the early 1970s, a feminist understanding of matriarchal pre- and early history and interest in ethnographic studies of matriarchal societies redeveloped.

Matriarchal Pre- and Early History

The question of matriarchal prehistory is especially associated with the Swiss jurist Johann Jakob Bachofen (1815–1887). In 1861 he published *Das Mutterrecht* (Mother Right), in which he proposed a theory of social evolution as a development from an era in which women were defenseless and degraded, followed by an era with mother-right and perfected in classical times with the rise of men and the "male principle." Bachofen, who actually never used the term *matriarchy* but *gynaecocracy*, revived the story of women-dominated societies in prehistory from classical Greek sources. The existence of matriarchies was explained by the assumption that some primitive peoples did not grasp the link between sexual intercourse and pregnancy. They therefore had no clear notion of paternity. When men discovered paternity, according to this hypothesis, they claimed the power to monopolize women and began to claim children as their own offspring. Hence, in 19th-century anthropology, women-dominated societies were regarded as a primitive stage of human evolution and patriarchy as an evolutionary advance. Bachofen was joined in this account by pioneers of the new discipline of anthropology along evolutionary lines (including Herbert Spencer). Socialists (e.g., Friedrich Engels)

and feminists (e.g., Charlotte Perkins Gilman) of these times were also attracted by the theory of prehistoric societies in which women dominated.

However, in the early 1970s, as part of second-wave feminism a feminist understanding of matriarchal prehistory came to be articulated. In this new tradition, *matriarchal* refers to women-centeredness, which does not deny equal power to men. This new feminist understanding of matriarchy is heavily indebted to archaeological finds that 19th-century scholars knew nothing about. Elizabeth Fisher, for example, used the early Neolithic site of Catalhöyük (located in present-day Turkey) to illustrate patriarchy's gradual encroachment into human society. Other scholars refer to the work of the Lithuanian/American archaeologist Marija Gimbutas, who argued for a widespread matriarchal (in the sense of woman-centered) culture in pre-Indo-European Old Europe of the Neolithic. In excavations in southeastern Europe, she uncovered a wealth of female figurines, which she identified as goddesses. Gimbutas's work is taken by some as proof of the claim that prehistoric societies were woman centered and goddess worshipping. However, some historians claim that this "evidence" is not reliable enough to allow for any conclusions. Nevertheless, women's status, role, and living conditions in prehistory and early history form a wide field of investigation in feminist and gender-sensitive anthropology, with new insights to be expected.

Contemporary Matriarchal Societies

Anticipating Bachofen, anthropologists and missionaries had begun to address the issue of female power as they encountered non-European societies in colonial contexts. They were shocked by senior priestesses and female chieftains. It was not later than 1724 when the French missionary J.-F. Lafitau expressed astonishment at the power of Iroquois women. Later on, Iroquois society was described by Lewis Morgan, who spent four decades studying them. Contrary to United States and European women in those days, Iroquois women spoke in council and selected the men who would be chiefs.

This early and more recent ethnographic data is referred to by supporters of the theses that there are (or, until recently, have in fact been) matriarchal (women-centered) societies among contemporary, scientifically observed, and documented societies. Due to the studies of anthropologist Bronislaw Malinowski,

the Trobriand Islanders have become one of the most frequently cited examples. He stated that mother-right is the most important and the most comprehensive principle of law, underlying all customs and institutions on the Trobriand Islands, an archipelago lying east of New Guinea in the Western Pacific. On the Trobriand Islands, kinship is established through females only (matrilineal descent). When a male reaches maturity, he goes to live in the village of his mother's brother. And while the father has a warm relationship with his children, it is the mother's brother who is responsible for them. Because of these and further characteristics, researchers like Heide Göttner-Abendroth, the most important German researcher on matriarchy, classify the Trobriand Islanders as matriarchal. The same holds for other matrilineal societies in Africa, Asia, the Pacific, and America. Examples include the Bemba and Luapula in Africa, the Nayar in India, the aforementioned Iroquois and the Hopi in America, and the Minangkabau—one of the largest ethnic groups in Indonesia.

Whether these societies are not only matrilineal but also matriarchal is a matter of debate. Most anthropologists sharply distinguish matrilineal descent from matriarchy and refuse the term *matriarchy* for these societies. They point to studies showing that matrilineal descent and the distribution of power, though interrelated, are separate. Descent theorists maintain that even in matrilineal societies, power and positions of authority are generally held by men (though transmitted through women) and that women can have a high status in patrilineal societies. Their opponents, however, argue that to focus on matrilineality or matrilocality is inadequate and hides the existence of matriarchies. They point to the fact that in most of these societies, it is not only matrilineality and/or matrilocality that can be found, but that in addition, the celebration of life stages (birth, initiation, marriage, death, ancestor cult) are women-only ceremonies, the Earth is seen as the creation of one or more goddesses, and so on.

Due to the disagreement on the meaning of the term *matriarchy* and its loaded history, alternative terms have been proposed, including *matristic*, *gynarchic*, or *matrix society*. Göttner-Abendroth continues to use *matriarchy* as a strategy to expose the sexist bias still ingrained in academia and the media, as does anthropologist Peggy Reeves Sanday.

MAUSS, MARCEL (1872–1950)

The French-born sociologist and anthropologist Marcel Mauss is best known for his analysis of gift-giving societies and their relationship to more modern economic systems. Mauss is often described as the father of modern French anthropology. Although Mauss did not conduct fieldwork himself, his focus on ethnology was instrumental in influencing members of disciplines such as sociology, philosophy, and psychology to recognize the benefits of fieldwork.

Although Mauss studied a wide range of topics, his most significant publication is *The Gift* (1925), which was written as his response to Lenin's New Economic Policy of 1921. Mauss observed the events in Russia and believed that because the market could not simply be done away with, revolutionaries needed to develop a more intellectual and complete understanding of the market economy. He wanted to determine where the market came from and whether there were alternatives to the market economy. At the time, most people believed that the goal of humans was to maximize their pleasure by accumulating goods that would increase their comfort. Therefore, it was thought that some form of the market economy must have always existed and would have, in its early forms, relied on barter exchange.

Using several different societies of Melanesia, Polynesia, and northwestern North America, Mauss examined the roles and functions of gift giving and discovered that barter did not exist in these societies. Mauss described the system of gift giving that existed in these societies and noted that gift giving was related to obligation in several different ways. There was an obligation to give gifts in certain settings, there was an

obligation to receive gifts that were offered, and there was the expectation that gifts would be reciprocated at a future date. Moreover, Mauss explained the competitive nature that often accompanied gift giving whereby the person who gave the gift received increased status. This was particularly the case with the potlatch system of societies on the northwest coast of North America. Therefore, Mauss illustrated the complexities inherent in gift exchange and the connections between gift giving and other aspects of society, such as religion, economics, politics, and mythology, while demonstrating that in some societies the goal was not to accumulate goods but rather to give away as much as possible so as to gain status.

At Bordeaux, Mauss studied philosophy and then later turned his focus to religion at the *Ecole Pratique des Hautes Etudes* (Practical School of Higher Studies). On completion of his studies, he was hired by his alma mater as a professor of primitive religion. From 1900 to 1902, Mauss taught Hindu and Buddhist philosophy at the University of Paris before becoming the chair of the Department of History of Religion of Primitive People, where he remained until 1930. Mauss, Lucien Lévy-Bruhl, and Paul Rivet worked together to found the *Institute d'ethnologie* (Ethnology Institute) at the University of Paris in 1925. Mauss lectured at the College of France from 1931 to 1939. He was influenced by his uncle and mentor, Émile Durkheim. Together, they founded the journal *L'année Sociologique* (The Sociological Year), in which Durkheim's theories and methodology were developed. On the death of Durkheim, Mauss became editor of the journal. Although Mauss worked on a minimum of five books on a variety of topics, including the origin of money, nationalism, and prayer, he did not complete any of these works.

Since ancient times, Mayan peoples have inhabited a region that included the easternmost states of Mexico, Belize, and Guatemala together with the western portions of El Salvador and Honduras. There are only a few parts of the world today where language and culture so closely coincide that a line drawn around the Maya-speaking peoples contains all of the archaeological sites and hieroglyphic texts assigned to ancient Mayan civilization.

Linguists have divided the 31 Mayan languages spoken today into three major subgroups: Huastecan, Yucatecan (Yucatec, Lacondón, Itzá, and Mopan), and Southern Mayan (Greater Quichean, Mamean, Kanjobalan, and Tzeltalan-Cholan). Each of these languages shares a common Proto-Mayan ancestor that was spoken in about 2000 BC in the highlands of Guatemala and Chiapas. It is through research with present-day speakers of Mayan languages that many of the new decipherments in hieroglyphic writing have been made possible.

While the Maya existed as a people for over 2 millennia, they developed a remarkably complex civilization over the span of 6-1/2 centuries (CE 250 to 900), in the rain forest of southern Yucatán and northern Guatemala. They built magnificent cities of stone pyramids, temples, and palaces, produced sculpture and paintings of remarkable aesthetic quality, and screen-fold books on paper. Reaching intellectual and artistic heights, which no other peoples in the New World could match at the time, they carved hieroglyphic inscriptions on monuments and used a writing system that has now been largely deciphered. They created a mathematical notation system more sophisticated than any of their European contemporaries, incorporating place notation and the concept of zero. They counted the passage of time in hundreds of thousands of years and developed a number of calendrical systems. At the center was a sacred calendar of 260 days composed of cycles of 13 numbered days and 20 named days. In addition, they had the *haab*, which was 360 days long plus 5 concluding, unlucky days. Another calendar was the *katun*, which was a cycle of 20 *tuns*, each consisting of 360 days. They also used a Venus calendar (584 days), a half-year lunar calendar, and other cycles. These calendars made the Mayas the most accurate reckoners of time before the modern period. All the days of these calendars were

recorded in astronomical almanacs that dictated religious ceremony.

These intellectual accomplishments were what made the “Mayan Classic period” into a kind of golden age during which the Maya, living in over 90 cities, were the only people in the Americas who used a phonetic writing system. Furthermore, they were the only civilization in the New World with chronological records going back to the third century AD. Many advances have been made in hieroglyphic decipherment, which has changed the view of the intellectual culture of the ancient Maya and modified our understanding of Classic Maya political systems. It has recently become clear that not all Mayan polities were equal. The kings of some lesser states were said to be “owned” by the rulers of more powerful states. While city-states such as Palenque and Copan exercised political control over some nearby areas, there were two superpowers, Tikal and Calakmul, that dominated the entire Yucatán peninsula during the Classic period.

The Mayan culture of this Classic period was characterized by hierarchal socioreligious institutions organized on both political and territorial bases. These complex institutions were mediated by monumental civic-ceremonial centers that concentrated royal authority, social stratification, and complex markets. Mayan agriculture was based on slash-and-burn farming, which required that a field be left fallow for 7 to 10 years after only 2 to 5 years of cultivation. Fixed raised fields and terraced hillsides were also used in appropriate areas. While the Mayan diet varied, depending on the local geography, maize was the primary staple, as it is today. Made nutritionally complete with the addition of lime, the kernels are boiled, ground on a metate with a mano, and formed by hand into flat tortillas. These are cooked on a griddle supported on three stones. Chili peppers, beans, and squash are also grown in the family farm plot, or *milpa*, together with the maize, maximizing each crop’s requirements for nutrients, sun, shade, and growing surface.

The Mayas enter world history with the appearance and spread of certain architectural styles. Limestone structures faced with lime stucco were the trademark of Mayan architecture. They also developed unique building innovations, including the corbelled arch, achieved by stepping each successive block, from opposite sides, closer to the center, capped at the peak. Tombs were enclosed within or buried beneath buildings. New temples were constructed over existing

structures. Roof combs towered above many structures, providing a platform base for stucco sculpture. In addition to temples, most Mayan sites had multi-roomed structures that served as royal palaces as well as centers for governmental affairs. Historically significant events, such as accessions, the capture or sacrifice of royal victims, deaths of kings, queens, and nobles, and the completion of 20-year katun cycles were recorded on stone stelae and tablets.

In Maya cities the ruling and noble class lived at the center, while most of the population resided in small farming villages at the periphery. Mayan nobility worshipped a complex pantheon of deities and other spiritual beings. Rulers were believed to be descendants of the gods, and their blood was the ideal sacrifice, either through personal bloodletting or the sacrifice of royal captives. The Mayan vision of the universe was divided into multiple levels, above and below the earth, positioned within the four directions. After death, the soul went to the underworld, or Xibalba, a place of fright where sinister gods tested and tricked their unfortunate visitors, but some souls escaped and rose as stars.

The dating of ancient Mayan civilization rests on the stratification of pottery, radiocarbon dating, native historical traditions passed on by postconquest writers, and the correlation of the Mayan and Gregorian calendars. The Maya Long Count, which is a daily calendar that has run from a point in the mythical past, began to be inscribed in AD. For reasons that we still do not well understand, the Mayas abandoned their cities around AD 900. There is evidence for invasion from the outside, and it is also possible that economic and environmental difficulties led them to abandon the cities. The greatest change seems to be the disappearance of most of the nobles. With this disappearance, the Mayas stopped building monumental cities, but the peasants continued to use the land on which they stood.

During the Postclassic, lasting from AD 900 to the Spanish Conquest, political power was wielded by councils of nobles rather than concentrated in the

hands of kings who were no longer celebrated in monumental inscriptions. Writing, which was now confined largely to books, saw an increase in the use of phonetic signs. Among the richest documentary sources from the colonial period are the katun prophecies of Yucatán, contained in the books of Chilam Balam, or “The Jaguar Priest.” They contain calendrical, astronomical, divinatory, mythological, historical, and medical information. Each book was named for its place of origin: Chilam Balam of Chan Cah, of Chumayel, Ixil, Maní, Kána, Tekax, Tizimín, and Tusik. The Chilam Balam of Nah, however, was named for the Nah brothers, from the town of Teabo, who signed the document. The history these books contain is based upon the Short Count, a cycle of

13 katuns ($13 \times 7,200$ days, or approximately 246 years) named for the Ajaw date on which it ended. Thus, for example, in Katun 13 Ajaw (AD 1262–1283), the Itzá Maya founded a new city, Mayapan, which was populated by provincial rulers and their families. This ensured their dominion over most of the city states on the Yucatán Peninsula. At about the same time, the K'iche' Maya established a large kingdom in the Guatemalan highlands.

The best early Spanish account of the Maya was written by Diego de Landa, who arrived in Yucatán in 1549. While he produced a long descriptive treatise about Mayan culture in Yucatán, he was also responsible for burning a large number of Mayan books because “they contained nothing but superstition and falsehoods of the devil.” Thus he destroyed much valuable ancient knowledge. Other important cultural and historical information survived elsewhere. The *Popol Vuh*, a manuscript written shortly after the conquest by the K'iche' Maya in Guatemala, gives the mythology and history of this group. The mythic cycle tells of hero twins who overcome earthly monsters and the lords of the underworld, making the world safe for human beings. They also established the ceremonial pattern for human birth, marriage, hunting, agriculture, and death.

The resilience of the living descendants of the ancient Mayas in resisting invasion, disease, exploitation, and repression is remarkable. Guatemala, which has the largest segment of the Mayan population (4 million), underwent a civil war during the 1980s. Guerrilla takeovers of hamlets triggered massive levels of state violence, during which the government engaged in ethnocide, if not genocide, against the Mayan population. They survived this purge and went on to organize themselves nationally in order to advocate for bilingual education. The Academia de las Lenguas Maya de Guatemala (ALMG) was founded, and Mayas, who were also trained as linguists, voted in new alphabets for writing their languages. Their ongoing activities include advocating for the use of these alphabets, encouraging ancient religious customs, the continued use of the ancient calendar, and the bar-and-dot numerical system. By so doing they are reinforcing their conceptual world, their ethnic identity, and their own time. The Maya have survived and will continue to survive into the foreseeable future.

MBUTI PYGMIES

The Mbuti Pygmies, referred to as BaMbuti or Bambuti, are an ancient group of hunters and gatherers living deep in the heart of Africa's Ituri Forest in what is today the Congo. It is speculated that they might be the earliest inhabitants of Africa. Often referred to as the forest people, the Mbuti, whose height rarely exceeds 4 feet 6 inches, have been mystified and romanticized by outsiders since the first written accounts provided by Egyptians around 2500 BC. Some have viewed the Mbuti in a utopian light, noting their egalitarian political and social structure, absence of warfare, sacred rituals, and close-knit social relationships with each other as well as their environment.

African Pygmies

There are a number of pygmy groups throughout Africa, such as the Twa and the Tswa, but it is the Mbuti who form the largest single group of pygmies and have retained their traditional culture for much longer than other pygmy groups. The Mbuti are divided into three primary linguistic-geographical groups—the Efe, the Aka, and the Sua—as a result of adopting the language of those villagers with whom they came into contact. Although there are some marked distinctions among these groups (e.g., some hunt with nets, whereas others hunt with bows and arrows or spears), they nonetheless share many similarities regarding polity, religion, family life, rituals, formalized relationships with villagers, and a current

trend toward assimilation with outsiders as globalization encroaches on their previously isolated home.

“The Mother and Father”: The Ituri Forest

The Ituri rain forest located in Africa’s Congo lies just north of the equator and covers approximately 70,000 square kilometers (43,496 square miles), an area roughly the size of the state of Wisconsin. It is a world of filtered sunlight under a dense canopy of trees that typically reach 100 feet, with some climbing to 200 feet, leaving the forest shaded, cool, and moist. A single, often impassable dirt road was built during the 1930s and cuts through the forest from east to west, isolating it from much outside influence. To outsiders, the Ituri is a dark and menacing place inhabited with malevolent spirits. Villagers are engaged in an incessant battle with the forest that threatens to overtake their fields. The Mbuti, on the contrary, view the forest as a parental deity deserving love and praise in return for providing them with all they need. For this reason, the Mbuti call themselves *bamiki bandura* (the children of the forest). The forest provides them with materials for shelter (geodesic dome-shaped huts made of saplings and covered with waterproof mongongo leaves), clothing (cloth made of bark and decorated with plant dyes), and food. The forest is the foundation of the Mbuti culture and shapes elements such as sociopolitical structure, economic production, and religion.

The Band

Hunters and gatherers live in small, mobile, politically autonomous groups known as bands. All members of a band are related to one another either directly or indirectly. Each of the Mbuti bands is dispersed over a large territory with a very low population density. As of 1958, there were only an estimated 40,000 Mbuti in the entire Ituri. The band has a territory that is geographically isolated from other bands and is able to provide sufficient resources for its inhabitants. In addition, fluidity of band membership helps to ensure appropriate band size to prevent outstripping resources while providing the group with enough people to hunt. Band members can move to other bands temporarily or permanently as they see fit. Ties of kin through marriage provide one type of link to other bands. Marriage is exogamous (band members are to marry outside of their own band), and so any

individual’s parents will come from two separate bands. Band size is also variable depending on factors such as seasonal variation in game and hunting style. During times of plenty, such as the honey season, Mbuti bands may break into smaller units while hunting is temporarily suspended. In general, band size is larger for net hunters than for bow and spear hunters.

Economic Production and Gender

Although techniques vary, all Mbuti traditionally have met their subsistence needs by hunting and gathering. The Mbuti make use of up to 100 species of plants and more than 200 species of animals, but the bulk of their diet consists of a smaller number of preferred plant and animal species. Women gather and men hunt, but men often gather while on the hunt if they see food that is especially good to eat, and women—especially among the net hunters—are a vital part of a successful hunt.

Among net hunters, men and women participate cooperatively in the hunt using strong nets made of a forest vine (*nkusa*) that average approximately 1 meter high and 30 to 100 meters long. Men form a large semicircle linking the individual nets, while women close in the other half of the semicircle driving game into the nets. Once an animal is caught in the nets, a man will spear it to death. Because they lack ways in which to store meat over a long period of time, excess meat is traded with villagers for plantation goods, but to hunt too excessively is thought to displease the forest.

Among bow hunters such as the Efe Mbuti, cooperation is also required for a successful hunt, but women do not participate directly in the hunt. Groups that bow or spear hunt do not generally capture as many animals in a hunt but require fewer participants. For this reason, bow and spear hunting bands generally average roughly 6 huts, whereas net hunting requires roughly 15 huts.

Regardless of the way in which a group hunts, securing food requires an average of only 4 hours per day four or five times per week. All meat is shared among the group members, but gathered foods, being more abundant and readily accessible, are kept primarily within the nuclear family.

Other jobs are also divided by gender as well. Men weave and repair hunting nets. Women weave the gathering baskets, cook, and build the family’s hut. However, gender divisions of labor are not strictly

maintained. There is no shame in a man cooking, and bachelors often cook for themselves. It has been suggested that women's contribution to subsistence explains their relatively equal status to men. Women have an equal voice in decision making and control powerful ritual knowledge.

Frequent trade with neighboring villagers may obscure the fact that the Mbuti need only the forest for their subsistence. Beyond a desire for luxury items, they require no outside materials for their survival. In exchange for meat, villagers provide the Mbuti with items such as metal cooking pots and cups, metal spear tips, and plantation foods. Plantation foods, far from being a necessity to the Mbuti, are not as healthy as forest foods. This is especially the case for consumables such as palm wine and tobacco. Even metal spear tips are not essential for a successful hunt and are often replaced by fire-hardened wooden spears.

Polity

The Mbuti have no chiefs or political leaders to threaten the solidarity of the group. Although knowledge and

skills of particular band members may be called on during times of need, there is no formal leader. In that cooperation by all members is essential for survival, group consensus is vital and the only political unit is the band itself. Division of the band into age groups further prevents centralization of power by dispersing responsibilities and decision-making authority. Decisions are made jointly, with the welfare of the band placed over that of any particular individual. The worst crime is to sacrifice the safety or welfare of the group. The ultimate punishment is the threat of ostracism from the band. Social inequalities are prevented in that the Mbuti do not individually own property, material possessions (beyond a hunting net or a particular cooking pot), or other resources.

Birth, Marriage, and Death

Birth for the Mbuti begins much as the rest of life will continue, that is, in a hut made of the forest surrounded by members of the band. A woman generally gives birth in her hut with the assistance of female kin. Sometimes a baby will be sprinkled with juice

from vines, which are then tied around the baby's wrist with a piece of wood from the forest. This helps to make the baby strong in that he or she is part of the forest. All men and women of the generation of the parents will help to raise the child, and all children his or her age will be considered brothers and sisters.

Marriage for the Mbuti is more or less monogamous and begins when a man and woman begin to live in the same hut, eating and sleeping together as a married couple. A man must seal the betrothal by demonstrating his hunting ability to the woman's parents. However, the marriage will not be official until the birth of the first child, and until that time the marriage may be easily dissolved.

Death is yet another transition for the Mbuti. Life ends in the same style hut and on the same type of sleeping mat into which the individual was born. The men dig a shallow grave in the hut and then collapse the roof on top of the body. There is a period of ritualized grieving where loved ones will mourn loudly, but this ends quickly so as not to offend the forest. The group then moves to a new camp. It is thought that the spirit of the deceased will join the spirits of other deceased Mbuti who live in the forest as they had lived in life, only invisible to those still alive.

Rituals and Religion

Unlike their village neighbors, the Mbuti do not practice witchcraft, sorcery, or magic, but they do have a rich tradition of ritual and religion. There are two central rituals of Mbuti culture: the molimo and the elima. The elima is a formal ritual to mark a young woman's first menses. This is a time of sexual freedom that may ultimately lead to her selection of a future marriage partner. All of the young women who have recently received their first menses will move to a special elima hut with a group of their close girlfriends. Here they are taught the elima songs as well as aspects of motherhood and sexual relationships. Far from being seen as a time of female pollution, the Mbuti view this as a joyous occasion marking a girl's transition to womanhood and thus motherhood. Sexual freedom is not, however, without some rules and limitations. The girls go out by day whipping boys as an invitation to the elima hut that evening, where they must fight their way through the girls' mothers and other older women to gain access to the hut. If a particular suitor is deemed unfit for any reason, he will likely be barred access. It has been

speculated that girls practice a natural form of birth control in that there have been no known accounts of pregnancy resulting from the elima ritual. At the end of the ceremony, the girls will take their place in Mbuti society as adult women.

One of the most important rituals for the Mbuti involves awakening and rejoicing the forest to restore order during times of death, prolonged periods of poor hunting, and other crises that threaten the social solidarity of the group. The molimo is both a tube-shaped instrument (capable of making a wide range of sounds) as well as a ceremony. The instrument is kept hidden from women and children and is brought out only at night for the duration of molimo festivals.

The molimo ceremony lasts approximately a month, and everyone cooperates by providing food and fire for the molimo hearth. Vigorous hunting during the day is followed by equally vigorous singing and dancing by the men at night. Men sing and dance throughout the entire night accompanied by the haunting sounds (often in imitation of the leopard) of the molimo trumpet. Dancing reaffirms the age group bonds at the same time that it affirms belief in the continuity of life and the band despite death. Women and children are secluded from the ceremony at night until the end of the ritual, at which time an old woman dances through the molimo fire, scattering it. This is to portray women as both givers and destroyers of life. The men quickly repair the fire. This dance reenacts the time when women originally possessed the molimo before men stole it. Both men and women are, therefore, regarded as central for a productive forest life. Regardless of the purpose for holding a particular molimo, the goal is to restore harmony by awakening and rejoicing the "mother and father" forest.

Contact With the World Outside of the Forest

The Mbuti's most enduring contact with the world outside of the forest is the relationship with villagers. It might appear that the Mbuti are subservient to villagers in that they are dependent on villagers for plantation foods, metal objects, and even for the substance of their culture. The villagers even refer to themselves as owners of the Mbuti. However, the behavior of the Mbuti when they are in the village mimics that of villagers only superficially and is quickly abandoned once they are in the forest. For example, in the village

the Mbuti have a “chief” who negotiates with villagers, but this individual has no authority over the band once the Mbuti are in the forest. The owner of one Mbuti might wish to marry “his” pygmy to a pygmy of another owner to create political and economic alliances. The Mbuti feign acceptance of this marriage solely so that they may enjoy the marriage feast that must be provided by the couple’s “owners.” However, once the Mbuti are back in the forest, the band does not consider the couple to be married.

The Mbuti participate in other village rituals such as the *nkumbi* (circumcision ceremony). Villagers believe that a boy must be circumcised to become a man and to be able to join the ancestors on death. Villagers involve the Mbuti in this ceremony so that they too will be able to go to the place of the ancestors and thus serve them on death. The Mbuti do not share the beliefs of the villagers, but they participate to gain the villagers’ necessary respect. For the Mbuti, it will be many years after the ceremony before the circumcised boys will be considered as adults. A result of the *nkumbi* is the bond of brotherhood between an Mbuti boy and a village boy who are paired through the *nkumbi* ritual. They are expected to trade with each other for life.

Current Trends and the Future of the Mbuti

It is tempting to view the Mbuti as a pristine group of exotic “others” yet untouched by modernity. However, significant contact first began some 300 to 500 years ago as agriculturists moved closer to the Mbuti, bringing new technologies and beliefs. Immigration of agriculturalists was followed by the Arab slave trade and colonialism.

During the colonial period, the Belgian administration enforced an increase in agricultural production of villagers with stiff penalties. Chiefs desperately sought “their” Mbuti to help them with the production. The Belgian government put much pressure on the Mbuti to leave the forest and to resettle as agriculturalists. At this time, the Mbuti remained able to escape into their forest world, but the seeds had been sewn for widespread change.

After the colonial period, the newly independent government of Zaire continued policies of forced resettlement but did so to emancipate the Mbuti, allowing them to contribute to the national economy by farming. They were to be given citizenship and thus subject to taxation. Model villages were constructed

to teach Mbuti how to be farmers. Unaccustomed to sedentary life, many became ill and died from contaminated water, nutritional deficiencies, and heat stroke.

By the early 1990s, the effects of globalization were becoming even clearer. The Okapi Faunal Reserve was created to protect the Mbuti and their traditional way of life by, for example, forbidding poaching of animals such as elephants and leopards. Civil wars and the erosion of political control of the Democratic Republic of the Congo, however, made enforcing these laws impossible. The forest has increasingly been cleared for agriculture, logged, and mined for its valuable natural resources such as coltan, a metallic element used in electronics. Such exploitation results in the loss of game and in pollution of the territory. No longer able to hunt and gather, the Mbuti are often compelled to work for cash wages, for the first time introducing sources of material inequality in the band.

The rich cultural traditions and lifestyles of the Mbuti are threatened as their forest foundation is increasingly destroyed. Many Mbuti youths today do not know of the *elima*, and they hunt excessively for surplus to sell. Previously sacred rituals not to be performed outside of the forest, such as *molimo* songs, have been brought into the villages. The future of the forest people described more than 3,000 years ago by the Egyptians hangs in the balance as the reach of globalization and modernization continues to expand.

McCOWN, THEODORE D. (1908–1969)

Theodore Doney McCown, an American biological (physical) anthropologist, is best known for three major contributions he made to his science. First is his study of the Neanderthal skeletons from the Skhul and Tabun caves in Israel and the publication of his work in 1939 in collaboration with the British anatomist Sir Arthur Keith (1866–1955), *The Stone Age of Mount Carmel: The Fossil Human Remains From the Levallois–Mousterian*. Second is McCown's pioneering program of research and teaching forensic anthropology as a professor at the University of California, Berkeley, during the mid-20th century when there were only a few other practitioners in this applied field of anthropology. At Berkeley's Department of Anthropology, he supervised more than 45 graduate students, with a considerable number of these students constituting the first generation of practicing forensic anthropologists entering academic and institutional positions. Third, McCown led two expeditions to the Narmada Valley of India (in 1957 and 1965), where he established the stratigraphic contexts of the alluvial deposits containing prehistoric stone tools of the Middle Pleistocene epoch.

Born in Macomb, Illinois, McCown moved with his family to Berkeley in 1913 when his father, Chester Charlton McCown, took the position of dean of the Pacific School of Religion. Later, when his father moved to Transjordan to serve as director of the Palestine Exploration Fund and conducted archaeological excavations at the site of Jerash, Theodore participated in the excavations. Theodore shared this interest with his younger brother, Donald Eugene McCown (1910–1985), who became recognized as an

authority on the archaeology of Persepolis and various ancient sites in Iran.

Theodore McCown's academic life began with his receipt of a B.A. degree in anthropology in 1929 from the University of California, Berkeley. The following year, he was again in the Near East as a member of the British School of Archaeology in Jerusalem, where he assisted Dorothy Garrod (1892–1968) in her ongoing excavations at the Mount Carmel caves. During his return visit to the caves in 1930, he was involved in the discovery of Neanderthal skeletons in the Skhul Cave. Additional skeletons were found there and at the adjacent Tabun Cave from 1932 to 1937. McCown and Keith undertook a collaborative study of the bones during this period after the fossils had been forwarded to the Royal College of Surgeons in London. McCown had entered his graduate program at Berkeley in 1930; hence, his studies toward the doctoral degree, awarded in 1939, coincided with repeated trips to the Mount Carmel region.

During the year he received his Ph.D. in anthropology, McCown joined the faculty of his alma mater, where the department was then under the chairmanship of Alfred Kroeber (1876–1960). McCown rose to the rank of full professor by 1951 and later served as chairman of his department, curator of physical anthropology at the Lowie/Hearts Museum, joint appointee to the Department of Criminology, and associate dean of the College of Letters and Science. During these years, he conducted archaeological excavations in Peru under the auspices of the Institute of Andean Research. But his academic career was interrupted by the military service from 1942 to 1945 when he was assigned duty in Graves Registration of the U.S. Army Quartermaster Corps at the San Francisco Presidio. His assignments included personal identification of war dead, certainly a stimulus to his postwar interest in practicing and teaching forensic anthropology at a time when the only academic instructors in this discipline were Earnest A. Hooton (1887–1954) at Harvard University and Wilton Marion Krogman (1903–1987) at the University of Chicago and later the University of Pennsylvania.

Among McCown's forensic cases were the identification of Junipero Serra (1715–1784) at the Franciscan Mission in Carmel, California; the identification of Juan Bautista de Anza (1735–1788), founder of San Francisco, in Arizpe, Mexico; and the negative identification of remains reputed to be those

of the American aviatrix Amelia Earhart (1898–1937) brought from a Pacific island to McCown's Berkeley laboratory. Other forensic anthropologists have continued identification of the “eminent dead” since McCown's death in 1969.

McCown's philosophy of teaching stressed the interface of biological anthropology and cultural anthropology, arguing that “man is a part of ‘brute creation’ [and] that the processes of organic evolution apply as well to man as other animals.” Sherwood L. Washburn (1911–2000) joined the Berkeley department in 1958, two decades after McCown had created the program in biological anthropology, and together they laid the foundations for the prominence of that field at their university.

McLUHAN, MARSHALL (1911–1980)

Herbert Marshall McLuhan was born on July 21, 1911. The proud parents sent out announcements heralding the birth with the saying, “Unto us a child is born, unto us a son is given.”

As a youngster, McLuhan was always quiet and retiring to the point of being antisocial. He had a great love of animals. “Rags,” an Airedale collie, was an integral and devotedly cared-for member of the family. In his earliest days at public school, McLuhan showed no promise as a future scholar. His report cards indicated marks ranging as low as 20% for spelling in Grade 3, borderline failures in other subjects, and few distinguished achievements other than in reading. At the end of Grade 6, he failed his year. But his mother Elsie, who was engaged in supply teaching at the time, prevailed on the teacher and school principal to give Marshall a chance in Grade 7. The probation was a success and more. His teacher, Mrs. Muir, proved to be the inspiration McLuhan needed, kindling the interest in English literature that would anchor his career. He put scholastic failure behind him but indulged himself in quirky spellings throughout his life.

At 10 years of age, McLuhan delivered newspapers. His route consisted of approximately 100 newspapers each day. The experience was encouraged by his mother to develop discipline and a sense of responsibility.

As he moved into his early teens, McLuhan began to shed his retiring nature. He played baseball and even formed a team from among the boys of the neighborhood, reserving the coveted position of pitcher for himself.

At 12 years of age, McLuhan became active in the Boy Scouts, participating for 2 years and earning his King's Scout. Scoutmaster Charles A. Hill recognized McLuhan's competence, and when guests were present, Hill invariably directed questions relating to scouting McLuhan's way, confident that he would have the answers.

When McLuhan was 17 years old, he acquired blueprints for a sailboat and enlisted friends to help build the 14-footer. Using a neighbor's garage, they set to work measuring, cutting, planing, and sanding, resorting to outside expertise only when the complexities of the spoon-shaped bow proved to be beyond them. In landlocked Winnipeg, they even managed to find 100 square feet of silk Egyptian sailcloth to ensure the lightness of the craft and improve its performance.

Sailing became a passion with McLuhan, a passion with a dimension he recognized as spiritual when he reflected on it some years later from the vantage point of Cambridge University. The passion for sailing led him to identify throughout his adult life with the sailor who survived the most harrowing of adventures in Edgar Allan Poe's story "A Descent Into the Maelstrom."

Beginning with a 1946 article titled "Footprints in the Sands of Crime," McLuhan would evoke the story of the Maelstrom many times in his writing and teaching. It figured prominently in the preface to *The Mechanical Bride*, with an explicit statement of its place and importance in the McLuhan method: "Poe's sailor saved himself by studying the action of the whirlpool and by cooperating with it."

The manual skill of young McLuhan the boat builder seemed to dictate a career. And the company of practical-minded friends exerted its influence as well. McLuhan joined them in enrolling in the engineering program at the University of Manitoba in Winnipeg in the fall of 1928. Before he had completed a year, however, McLuhan discovered that he

was not in his element. Then, as he worked at a summer job among engineers, his misguided choice was confirmed. Some of his coworkers simply ignored McLuhan as he spent every free moment reading, whereas others resented the presence of the lean, self-absorbed 6-footer. In the fall of 1929, he switched to a 4-year B.A. program that would focus on English, history, and philosophy. The excitement of setting out on his intellectual odyssey was dampened as soon as McLuhan saw how vast a job it would be to master a domain he wanted to stake out. And nothing less than mastery would satisfy him. He set his own program of reading and developed his own uses for what he read. "I have to read outside the course to maintain interest," he confided in his diary. Thomas Carlyle was an early favorite because of his bold innovative language. After Carlyle, Thomas Macauley and Samuel Johnson would beckon McLuhan to the heights of greatness. Later still, Trevelyan, Boswell, Thackeray, and Shakespeare did likewise.

By 1936, McLuhan had completed his university studies, and his options were teaching English in Wisconsin, being unemployed, or turning his life in a new direction. To be jobless after 8 years of university study was unthinkable, and the memory of hardships suffered by those around him during the worst of the Depression years in Winnipeg—hardships that the McLuhans themselves managed to escape—was still too vivid.

On September 9, 1937, McLuhan left Wisconsin for a new teaching position at St. Louis University. He was moving to a larger city, to a larger university, and with a larger perspective. McLuhan thrived on intense mental stimulation. St. Louis held the promise of satisfying that need and soon delivered on it.

McLuhan was awarded his M.A. degree on January 20, 1940. Although his time at Cambridge was nearly over, it was a day for looking to the future more than for reminiscing. The return trip to America would require careful planning. A transatlantic crossing during wartime meant restrictions and complications.

On December 11, 1943, McLuhan earned his Ph.D. degree from Cambridge in absentia due to the war. From that point onward, McLuhan's career exploded. By 1970, he was an international celebrity. In 1972, McLuhan made more than 30 appearances in person and on television, addressing audiences with his blend of entertainment and education. He spoke to teachers and writers, clubs and power brokers, medical doctors and business managers. But he aimed

few remarks at their particular interests and made no concessions to those unwilling to be jolted into awareness of media effects by his inseparable weave of style and message: “Sputnik put an end to nature, turning the earth into an art form and the planet Polluto. . . . Roles have replaced goals. . . . We put on our technology as evolutionary clothing. . . . Childhood was unknown to the Middle Ages—it began in the Renaissance with painting and ends now in the TV age.”

By 1973, McLuhan had collected eight honorary doctorates, been made a fellow of the Royal Society of Canada, received the Christian Culture Award from Assumption College, received the Gold Medal Award from the president of the Italian Republic in recognition of his work as a philosopher of the mass media, received the President’s Cabinet Award from the University of Detroit, and been appointed by the Vatican to the Pontifical Commission for Social Communications.

Although the story of McLuhan’s life is an intellectual odyssey, the hero was no wandering Ulysses. In retrospect, the coherence of his work becomes apparent; it stems from his genius for returning constantly not to a single point but rather to a single strategy—probing and testing the forms and limits of an idea, forging links among ideas, developing a method for escape into understanding. This he did by using the prison walls of language as ramparts. In his book *Understanding Media*, McLuhan referred to language as humankind’s first technology for extending consciousness. It is the technology that has both translated thought into speech and been translated by a succession of other technologies throughout the course of civilization (e.g., hieroglyphics, phonetic alphabet, printing press, telegraph, phonograph, radio, television, telephone). Language was central to McLuhan’s teaching on media, their transformations, and their interactions.

McLuhan, realizing that electronic technology does not depend on words, saw further. The computer is the extension of the central nervous system. It offers the possibility of extending consciousness without verbalization, of getting past the fragmentation and numbing effect that makes the Tower of Babel the counterpart to Pentecost, of providing a way in which to achieve universal understanding and unity. McLuhan’s intellectual ferment emphasized the training of perception and prepared the way for the innovations that marked his thought until the end of his life.

McLuhan loved to teach, write, and lecture in public about the intellectual investigations of his life. A summary account of these investigations is given next, with McLuhan’s probes serving as section headings.

Acoustic Space

Acoustic space was a key topic for McLuhan. The idea was developed by E. A. Bott in the Department of Psychology at the University of Toronto, and news of it came at an interdisciplinary seminar. Although McLuhan never met Bott, he acknowledged Bott’s work as a stimulus for his own “study of olfactory space, and the rest.” Writing to one of his friends, McLuhan brought faith, physics, philosophy, and language through the vanishing point by way of acoustic space: “The ear creates acoustic space whose center is everywhere and whose margins are nowhere. This has often been mistaken for God by tribal societies as well as by neo-Platonists and the Oriental world.”

Figure and Ground

In the early pages of *Understanding Media*, McLuhan referred to “the unified ‘field’ character of our new electromagnetism.” Only his quotation marks around “field” hinted that the familiar world has a special meaning. Much later in the book, McLuhan discussed the automobile and how it “has quite refashioned all of the spaces that unite and separate men.” Figure ground eventually became his favored probe. The automobile could now be described as a figure against the ground of highways, service stations, motels, billboards, drive-in theaters, and suburbs.

Effects

The study of effects is the thread running through all of McLuhan’s media analysis, if not its entire rationale. It takes its roots in his training in practical criticism, where McLuhan learned to heed I. A. Richard’s call to “give a fuller and more entire response to the words” of poetry and to develop “the fullest realization of the varied powers upon us.”

Causes

By the end of his life, McLuhan had long since become an iconic figure in a world that knew little of

his percept that the iconic merges figure and ground. But the popular consciousness of McLuhan the icon had earned him a limerick for his pronouncements on the merging of effect and cause:

Runs one of McLuhan's mad laws,
The effect always precedes the cause.
Thus the baby's produced,
Ere the maid is seduced;
Is it impertinent to ask who the pa is?

If the question does not invite a serious answer, McLuhan nevertheless supplied one, naming a hardy reincarnation of efficient causality as the offspring of print. To this, McLuhan added a rare plain statement of definition: "But I refer to formal cause not in the sense of classification of forms, but to their operation upon us and upon one another."

Structuralism

McLuhan's thinking during the 1970s, particularly during the middle years of the decade, was dominated by his own unique brand of structuralism. McLuhan had already outlined structuralism in the broadest terms—the trend of modern thought, in areas as diverse as physics, painting, and poetry, whereby "specialized segments of attention have shifted to total field." Structuralism appealed to McLuhan for its own merits and because it invited the type of interdisciplinary inquiry to which his own natural bent led him.

McLuhan died on December 31, 1980.

GLOBAL SOCIETY

With the Internet drawing people together from all quarters of the world in an electronic community, the idea of such a global society had its first appearance in the work of Marshall McLuhan, who was director of the Center for Culture and Technology at the University of Toronto. With his *Understanding Media*, published in 1964, McLuhan confronted what he felt was a rapidly moving culture that was still trying to explain itself using the same printed mode of communication that had been in vogue since the invention of the printing press by Johannes Gutenberg in 1455.

Contrary to most people of his time, McLuhan perceived the revolutionary paradigm shift that had occurred with the globalization of communications through the new media of television. Even more, he saw the effect on both information and education as prefigured by the instantaneous delivery of information made possible by communication satellites. Indeed, 2 years before the publication of *Understanding Media*, the first true communications satellite, Telstar I, was launched on July 10, 1962, and on that same day live television pictures originating in the United States were received in France.

McLuhan saw in the revolutionary communications growing around him the means to break down the parochial barriers of class, language, and even nations themselves and to form in their place a vibrant "global village." The information that would be at hand in the global village, in McLuhan's view, would free humankind from the provincial tribalism that had been at the root of human bloodshed and suffering over the centuries. As McLuhan wrote, "In this electronic age, we see ourselves being translated more and more into the form of information, moving toward the technological extension of consciousness. That is what is meant when we say that we daily know more and more about man. We mean that we can translate more and more of ourselves into other forms of expression that exceed ourselves. Man is a form of expression who is traditionally expected to repeat himself and to echo the praise of his Creator.

Man has the power to reverberate the divine thunder by verbal translation."

Within 30 years, McLuhan's vision of a communicating global village had been realized dramatically. During the Gulf War of 1990–1991, the cable TV network CNN, with its heavy reliance on satellites and its innovative 24-hour daily news coverage, became the medium to watch for the unfolding of the war. Indeed, not only did it become the main way in which the American public learned of the progress of the war, but also the American armed forces watched CNN to monitor their own progress in operations against the Iraqi army. Within 5 years, the Internet enabled people with like interests and needs to communicate over thousands of miles literally within seconds, forming virtual communities of people who, due to physical handicap or sheer distance, would otherwise have remained isolated. By 2005, the first part of McLuhan's message, the creation of a virtual community, had been realized. The second part, the quest for his global village to help realize the pacific and loving intentions of humankind's Creator, still remained elusive.

MARGARET MEAD (1901–1978)

Margaret Mead, the most prominent and recognized anthropologist of the 20th century, had a profound influence on anthropology and feminism. She achieved celebrity status and became an American oracle.

Mead was born into a Quaker family in Philadelphia on December 16, 1901, the daughter of Edward Sherwood Mead (a professor of economics at the University of Pennsylvania Wharton School) and Emily Fogg Mead (a sociologist and suffragist). Margaret had lived in 60 houses by 6 years of age. She attended DePauw University (1919–1920), graduated with a B.A. degree from Barnard College (1923), and received her M.A. in psychology from Columbia University (1924) and her Ph.D. in anthropology from Columbia University (1929) studying under Franz Boas and being mentored by Ruth Benedict.

While establishing her home base in New York City, Mead was appointed curator of ethnology at the

American Museum of Natural History (1926), associate curator (1942), curator (1964), and curator emeritus (1969). She was appointed adjunct professor of anthropology at Columbia (1954–1978), professor of anthropology while she founded the department at Fordham University (1968), visiting lecturer in the Department of Psychiatry at the University of Cincinnati School of Medicine (1957–1958), and visiting lecturer at the Menninger Foundation in Topeka, Kansas (1959).

Diminutive in stature yet strong in character and stamina, Mead was never known to shrink from controversy. She wielded proclamations of her field research findings in anthropology, her feminist opinions on the role of women, and her recommendations regarding sexual liberation, marriage, and marijuana decriminalization. She carried a big stick—a forked walking stick—and spoke other than softly (an interesting contrast to Boas's nemesis, President Theodore Roosevelt). She seemed larger than life. Only Benedict knew her well. They became intimate friends in their roles as mentor and student, and Mead became the child Benedict never had. She became absorbed in Benedict's work and internalized the theory of cultural relativity.

Mead's findings in her field studies were provocative. Having obtained a National Research Council fellowship (1925) while on staff at the Museum in Honolulu, she traveled to the island of Tau in Samoa to verify Boas's hypothesis that culture and not biology influences adolescent behavior the most. The product of this research, *Coming of Age in Samoa* (1928), caused a public stir due to her descriptions of unrepressed adolescent Samoan girls' sexual activity compared with that of American girls as well as her recommendation that Americans could learn how to raise children from Samoans. The stir was heightened when some colleagues claimed that Mead ignored biological factors in her emphasis on the theory of cultural determinism. At the time, she was married to but separated from Luther Cressman, and she then met and married Reo Fortune (1928), with whom she traveled to Manus and the village of Peri in the Great Admiralty archipelago.

Mead's work in Peri led to *Growing Up in New Guinea* (1930), in which she argued that the difference between the "civilized mind" and the "primitive mind" had been exaggerated; human nature was malleable. The work was highly received and inspired her to study the Omaha Indians of Nebraska (1930),

followed by research in Alitua, New Guinea (1931). There, Mead developed a typology of aggression based on the pacifist Arapesh mountain people and the violent Mundugamour village people, and she also studied the Tchambuli people while living with the Washkuk tribe. Her typology was a major contribution to the theory of cultural relativity.

Following a divorce from Fortune, Mead married ethnologist Gregory Bateson (1936). They conducted 2 years of fieldwork in Bali, where they used photography in research and annotated more than 25,000 photographs, many taken of the Balinese ritual of trances, a fundamental element in Balinese culture (“Trance and Dance in Bali” in *Balinese Character: A Photographic Analysis*, 1942).

In 1944, Mead and Benedict collaborated to form the Institute for International Studies to analyze contemporary societies from which salient elements could be incorporated into a new world order.

Mead’s prolific writings include *And Keep Your Powder Dry: An Anthropologist Looks at America* (1942); *Male and Female: A Study of the Sexes in the Changing World* (1949); *New Lives for Old* (1956); *Culture and Commitment: A Study of the Generation Gap* (1970); and her autobiographical *Blackberry Winter: My Early Years* (1972). Feminism is a recurrent theme throughout her writings. She had a demonstrable sense of adventure and heroism along with a disdain for the passive cultural role of women in the United States. Her focus on women’s gender roles in cultures and child rearing spotlighted her as an influential leader of feminism and women’s liberation while she defended women’s right to develop their talents in humanities and intuition. She became one of the most recognized leaders of the women’s movement of the 1960s. Whereas her mentor Benedict was introspective and a role model of feminism through her work, Mead was an extrovert who exhorted women’s liberation. She gave more than 100 speeches every year, wrote for *Redbook* magazine, and was unswerving about her opinions.

Of particular interest is Mead’s experience with her daughter and only child Mary Catherine, who was born in 1939. Mead insisted on natural childbirth, which she had observed in her field research, and she wanted the birth to be filmed and recorded. She

enlisted the cooperation of pediatrician Benjamin Spock, and the event gained national attention. Mary Catherine Bateson Kassarian became an anthropologist and dean of social sciences at Raza Shah Civar University in Iran.

Mead received many kudos, including election to president of seven professional organizations, for example, the World Federation of Mental Health (1956–1957), the American Anthropological Association (1960), and the American Association for the Advancement of Science (1975). She received UNESCO’s Kalinga Prize. She died of pancreatic cancer on November 15, 1978. *Time* Magazine’s obituary of Mead was titled “Grandmother to the Global Village.”

MARGARET MEAD

Margaret Mead was a cultural anthropologist whose studies advanced ideas about “primitive peoples,” human growth, race, and issues of cross-cultural developments. Mead viewed human diversity as a form of social wealth.

Mead was born into a family of social scientists in Philadelphia on December 16, 1901. She studied psychology at Barnard College and eventually earned a doctorate at Columbia University under anthropologists Franz Boas and Ruth Benedict.

In 1925, she went to American Samoa to do fieldwork on the behavior of adolescent Samoan girls. She published a description of her work in *Coming of Age in Samoa*. The book, translated into many languages, became a best-seller.

In *Coming of Age in Samoa*, Mead said that the early stages of human development can be shaped by the culture in which a young person lives. The implications were that young people do not all experience childhood and youth in the same way because culture conditions human biology.

In 1929, Mead went to Manus Island in New Guinea to study the ways in which adult society in New Guinea influenced the development of children. Her work on Manus Island was published as *Growing Up in New Guinea*. The Manus Island work changed the views of many people that

“primitive peoples” were like children. She was the first anthropologist to look at human development in a cross-cultural perspective.

During World War II, Mead was unable to continue her New Guinea research due to the fighting in the area. With Benedict, she founded the Institute for Intercultural Studies. The goal of the institute was to apply anthropological methods to the study of contemporary culture.

In 1953, Mead returned to Manus Island to continue her studies. She reported her work in the book *New Lives for Old*, in which she said that people could choose to work out futures that were different from those that seemed mandated by current social arrangements.

In subsequent fieldwork on the mainland of New Guinea, Mead showed how different societies have different gender roles that are a product of both biology and the local culture. She did similar work on Bali.

Mead published numerous works, including *Science and the Concept of Race* (1968) and *Culture and Commitment: A Study of the Generation Gap* (1970). In 1972, she published *Blackberry Winter: My Early Years*, which is an autobiographical work. In 1977, shortly before she died, she published *Letters From the Field: 1925–1975*.

MUNDUGAMOR

The Mundugamor are a primitive society living in New Guinea. In 1932, the American anthropologist Margaret Mead and her husband, Reo Fortune, set out to study three tribes in New Guinea: the Arapesh, the Mundugamor, and the Tchambuli. The three tribes all lived within a 20-mile radius of one another. However, gender roles were perceived entirely differently in each of the three tribes.

In the Arapesh society, both male and female children were taught to be warm, cooperative, and nurturing. Both men and women exhibited what one would call feminine traits. They believed that men and women were equal, and both were actively involved in raising their children. According to their history, they had always been that way.

Mead and Fortune traveled up the Yuat River to the village of Kinakatem, where the Mundugamor live. The 2½ months that Mead spent with the Mundugamor gave her important evidence to support her conclusions in her well-known book, *Sex and Temperament in Three Primitive Societies*. She found that both the males and females of the Mundugamor tribe exhibited what one would call masculine characteristics. She described both men and women as assertive, violent, individualistic, and volatile. Men and women had different social roles, but their personality characteristics were the same. Mead described the ideal Mundugamor male as "a lion fighting for his share . . . surrounded by several equally violent lionesses." The Mundugamor behaved in a hostile and aggressive manner toward outsiders, their own tribe, and even family members. Mundugamor children were often left to fend for themselves. Mead was alarmed to find that infants of the "wrong" sex were often thrown into the river to die.

The third tribe that Mead studied was the Tchambuli, whose people practiced gender roles opposite to those in American society. The women were dominant, the principal workers, and the sexual aggressors. The men were reported to be irresponsible, vain about their appearance, and dependent on the women.

From her study of these cultures, Mead concluded that gender roles are not the result of a

person's sex. She came to the conclusion that gender roles are determined by socialization and learning. Children follow the patterns set by adults of their sex and become like them.

MEDICAL GENETICS

Medical genetics is the study of the interrelationship between human biological variation, including both genetic and environmental sources, and the phenotypic outcomes of health and disease. The field has rapidly moved to the forefront of biomedical research. Its overall goal is the detection and treatment of pathological genetic variation. In the past, medical genetics focused on genetic disorders such as chromosomal and single gene conditions, but increasingly medical geneticists are studying common diseases to which genes contribute significantly such as cancer and cardiovascular disease.

The prospect of preventing many diseases seems attainable today with the sequencing of the human genome and the application of genomic techniques to the characterization of disease-related genetic variation and specific mutations. The ultimate goal is to understand how genes contribute to an individual's susceptibility to disease and the individual's responses to the disease and to treatment. Identifying disease-associated genes, identifying novel molecular and genetic targets for chemotherapeutics, and even correcting defective genes through gene therapy hold tremendous promise in medicine. This promise, however, is feared to be advancing faster than society's ability to cope with the ethical considerations concerning what should be done with genetic information and specifically the genetic profiles for disease. The question lingers about how far society should go in modifying an individual's genetic makeup for any reason.

Eugenic concerns aside, medical genetics has revolutionized modern approaches to understanding and treating disease. Using a multidisciplinary approach to studying disease, the tools of medical genetics, genomics, and anthropology can produce a synthetic picture of a disease never attainable previously.

With the completion of the Human Genome Project, disease-associated genes are being discovered at an astounding rate while, at the same time, ancestral characteristics of populations are being defined at the genetic level. The latter are important in our understanding of the global and regional distribution of diseases among ethnic populations and the evolutionary and other contributors to disease variation among populations, a traditional research area in biological anthropology. Many of the disease-related genes and their inheritance characteristics have been made publicly available through online registries such as the National Center for Biotechnology Information (NCBI) and specifically the Online Mendelian Inheritance in Man (OMIM).

Sickle cell disease is a well-described example of studying a disease-causing gene at the population and individual levels and including the perspective of the environment. The mutation that results in the formation of hemoglobin S rather than the normal hemoglobin A causes a severe disease among individuals who are homozygous for the mutation, whereas the same mutation confers resistance to malaria in heterozygous individuals. Within malaria endemic regions, the mutation is maintained at relatively high rates through balancing selective pressures, that is, through the higher fitness (reproductive output) of heterozygous individuals in comparison with the two homozygous genotypes. Sickle cell disease is important in that it is probably the most completely researched example of natural selection in human populations. It is also a prime example of a genetic polymorphism, where the mutation is maintained in the population by selection. However, in African American and other populations no longer living in areas where malaria is endemic, such that there is no evolutionary advantage to this mutation, the frequency of the mutation is decreasing through relaxed selective pressure as well as admixture with other populations.

With the further discovery of genetic variation and specific mutations in the common diseases such as cancer and heart disease, medical genetics will play a key role in the detection, treatment, and prevention of disease as well as in the general understanding of human health. During the next 20 years or so, we will likely achieve for some of the complex diseases, such as diabetes and hypertension, the level of understanding that we have today about sickle cell disease. Combining information from diverse fields, including

anthropology, furthers this understanding, forming a more complete picture of the complex relationships among heredity, environment, and behavior in the development and management of disease.

MEDICINE MAN

The term *medicine man* is derived from (a) the French Jesuit observance of certain individuals with healing roles among Canadian Indian groups (medicine) or (b) the Inuit *angakoq* or medicine person. The term is usually considered an anachronism in contemporary anthropological literature, with the Siberian Tungus word *shaman* preferred in most cases. However, among contemporary Native Americans, the preference remains to refer to individuals with a healing and sacred function as medicine men/women. The term *medicine* itself is a descriptor of a wide range of psychological, physical, and spiritual knowledge that aids in the restoration of balance and equilibrium within the indigenous worldview.

References to medicine men in the literature often assume the phenomena particular to preliterate small-scale societies. Early documentation of the practices are found in the writings of explorers and missionaries (e.g., Soares de Souza in 1587) and was used to describe healers such as the “medicines” of the Topamambos, *heyoka* (Sioux), False Face Society (Iroquois), *Hataal* (Navajo), *Midewiwin* (Great Lakes), *Waken* (Lakota), and leaders of the Native American Prophetic movements (e.g., Neolin, Handsome Lake, Smohala, Wodziwob, Wavoka) as well as practitioners in Africa, Oceania, and Asia. The distinctive element in all cases was the skill at performing ritual healings to restore cultural and ecological equilibrium to the

particular group. The continued importance and revival of many of these roles in literate postindustrial areas illustrate the cultural depths of the medicine way in spite of efforts by missionaries and governments to eradicate the practices.

Arnold Van Gennep's work on the role of medicine men divided their functions into the realms of religion and society. This is most evident in societies such as the !Kung and the Australian Aborigines, where more than half of the adult males are considered to be medicine men. The role of these medicine men, however, includes trances and altered states of consciousness. Victor Turner's work on religious specialists separates these roles and functions and makes a distinction among priests, shamans (or medicine men), and media. These distinctions can blur, however, from society to society. In addition, as Claude Lévi-Strauss demonstrated, medicine men can be equally adept at healing and at performing witchcraft. A more nuanced view of the medicine role is that suggested by writers such as Gerardo Reichel-Dolmofoff, who view that function as an ecological balance for hunting, fishing, and gathering activities.

The key to understanding the phenomenon of medicine people lies in the worldview of those societies. The world is understood as a holistic entity, with the entire world imbued with spirit. In this animistic view, all of creation has moral agency, and the human is integral to the long-lasting efficacy of all of life. For some groups, such as the Navajo, the power of the human is a unique quality that flows from the holiness of words. Thus, singers (*hataal*) continue the work of creation and balance. In other groups, the medicine people are grouped together in societies so that their combined spirits might bring about the desired effects (e.g., Zuni). In every case, the role of magic is essential, and the notion that the human can influence spirits through words and action is at the heart of being a medicine practitioner. In this way, a medicine man is an expert in techniques of contagious and sympathetic magic.

The term *medicine man* can be misleading in that it implies a gender-specific role. Most cultures that have medicine men also recognize women's ability to minister and heal and to become medicine practitioners. However, many women do not attain full status and recognition until menopause because menstruation is often viewed as a power unto itself.

Medicine men can achieve their position through (a) inheriting the position through blood lines, (b) being called through visions, (c) being recognized

by others as being specially gifted, and (d) being self-selected to enter training. In most cases, training is undertaken with a well-established medicine man and can take years before one is recognized as a healer. Much of the training involves learning the legends and myths of the group, rituals and ceremonies, and the animals, plants, herbs, minerals, and so forth that are used in the healings. The public role of the medicine man is to be at service to the whole group, and individuals that attempt to gain prestige, power, or personal wealth are often shunned.

MEGANTHROPUS

In 1949, based on the large size of a single mandible, G. H. R. von Koenigswald named a new hominid genus *Meganthropus*. Today there is no agreement

among the authorities concerning the taxonomic status of the mandibular specimens that have been assigned to the genus “*Meganthropus*.” Despite morphological differences related mostly to extreme size, most authorities have assigned these mandibles to a proposed highly sexually dimorphic population of early *Homo erectus* in Java. New evidence of cranial material has made this proposal even more problematic. Sangiran 31 consists of nearly complete left and right parietals, part of the left temporal, and an occipital. It also possesses a double sagittal ridge. The overall morphology of Sangiran 31 is different from that of any known specimen of *H. erectus*. An undescribed specimen, Sangiran 27, consists of a nearly complete but crushed cranium. The palate and dentition are intact and are within the size range found for the *Meganthropus*-type specimen and outside the range of known *H. erectus* specimens. Most classifications place *H. erectus* only in Asia. What was previously referred to as *Homo erectus* in Africa is now referred to as *Homo ergaster* and in Europe is referred to as *Homo heidelbergensis*, *Homo atapuerca*, and *Homo antecessor*. The specimens that have been placed in *Meganthropus* are morphologically different from the newly named species of *Homo* in Europe and Africa. The *Meganthropus* specimens probably represent a speciation event from *H. erectus* in Java and should be referred to as *Homo meganthropus*.

MEHAN, HUGH

A sociologist by training, Hugh (“Bud”) Mehan has made important contributions to the anthropology of schooling, particularly with regard to language use and the construction of students’ academic identities. He has published on topics as diverse as the scaling up of school reform, the pedagogical use of computers, and the discourse of the nuclear arms race, but he is best known for his critical analyses of ability grouping (“tracking”), whereby schools segregate students on the basis of their (supposedly innate) academic talent. As director of the Center for Research on Educational Equity, Access, and Teaching Excellence (CREATE) at the University of California, San Diego, he has applied his research findings to improving the education of underserved groups through initiatives in teacher education and university partnerships with K–12 schools.

A substantial amount of educational research has been dedicated to evaluating the effectiveness of tracking and devising appropriate pedagogies for variously tracked students, but relatively little has questioned the processes by which students are assigned to the academic categories that effectively define their futures. During the latter half of the 20th century, anthropologists and other social critics began to question the institutional practices that relegated disproportionate numbers of African American, immigrant, and low-income students to lower academic tracks. Ethnographic studies revealed that low-tracked students also tended to receive a lower quality of instruction, with fewer opportunities for academic and intellectual development and little chance of mobility within the academic hierarchy. Rather than taking academic evaluations of students’ intellectual abilities at face value, Mehan and other scholars sought alternative explanations for the ethnic and

economic stratification that is manifest in the distribution of “ability groups.”

While numerous critics of tracking have cited possible cultural bias in academic testing, Mehan focused on the school’s construction of academic identities, such as “the competent student,” “the learning-disabled student,” and “the genius,” and examined the institutional processes by which various educational actors (e.g., teachers, parents, counselors, administrators) collectively assign academic identities and future trajectories to individual students.

As a remedy for the social and educational inequities perpetuated by tracking, Mehan and his colleagues proposed “untracking,” that is, providing all students with the same academically demanding curriculum while giving underserved students the institutional scaffolding and support they need to navigate the school’s “hidden curriculum.” Mehan argues that by intellectually challenging all students and engaging them in critical reflection on their own schooling, previously marginalized students can transition to college successfully without sacrificing their cultural identities. Employing techniques of ethnography, ethnomethodology, and discourse analysis, he has analyzed educational practice in terms of cultural representations. However, his work is not limited to theoretical formulations of identity construction. Rather, he engages the practical consequences of both tracking and untracking for students’ educational careers.

Mehan’s work on large-scale school reform, although broader in scope than his fine-grained classroom studies, shares the same concern for applying the theoretical insights of anthropology to the concrete goal of improving students’ life chances. His analysis of the discourse of the nuclear arms race likewise manifests his commitment to social justice and the critical deconstruction of “official” representations of society.

Mehan is a member of the National Academy of Education and the recipient of various teaching awards. He has served on the executive council of the American Anthropological Association and as vice president and president of the Council on Anthropology and Education as well as on the editorial boards of numerous journals on language use and educational research, including the *Anthropology and Educational Quarterly*.

Throughout antiquity, skin coloration has had a tremendous impact on humanity, causing various health effects along with discrimination and racism of ethnic groups. Melanin is a pigment that has been naturally selected to help humans adapt to different geographical regions and selective pressures. Variations in skin coloration, the amount of melanin in the skin, are related to the amount of ultraviolet (UV) radiation and nutrient synthesis in the body. A common misconception is that differences in skin pigmentation have a biological basis in distinguishing among “races.” Today, we now understand that with a high correlation between latitude and UV levels, most variations in skin coloration are due to differences among geographical regions.

Evolution of Skin Coloration

Many anthropologists believe that the earliest hominids were covered in dark black hair with low or unpigmented underlying skin. Various models have been produced to show human evolution and the adaptations that favor increased levels of melanin in the skin. During the transitional period, it was thought that the need for thermoregulation led to a decrease in body hair and a subsequent increase in

sweat glands. Because the brain is heat sensitive, these mechanisms allowed for increased activity in growth. In response to a decrease in hair covering, the body adapted by increasing melanin production in the skin to protect against the harmful UV radiation. Throughout human evolution, skin pigmentation has continuously varied and adapted depending on the selective pressures. As a result, skin pigmentation cannot be used to track or determine evolutionary development of humans today.

Melanin Production

Melanin is a pigment that helps to determine skin, hair, and eye color. It is also found in the medulla, the zona reticularis of the adrenal gland, the inner ear, and the substantia nigra of the brain. The production of melanin depends on the enzyme tyrosinase that converts the amino acid (building block of protein) tyrosine into dopaquinone. The dopaquinone molecule is then transformed into a variety of colored pigments. It is the Golgi organelles of the melanocytes that package melanin into vesicles called melanosomes. These vesicles are then shipped into the cell processes (extensions) of the melanocyte, where the processes are ingested by keratinocytes (cells of the epidermis that produce keratin). Thus, the melanin has been transferred from the melanocytes into the keratinocytes of the epidermis (outermost) layer of the skin.

There are a few different types of melanin in the human body. Eumelanin is the most abundant type and is found in skin and hair. Pheomelanin is less common but is responsible for the reddish tone in red hair and is also found in skin. Lastly, neuromelanin is found in the substantia nigra region of the brain and is a dopamine by-product.

Genetic Polymorphism and Natural Selection

Skin pigmentation is one of the most variable human characteristics; however, little is known about its genetic and evolutionary paths. Skin color is a polygenic trait that is controlled by the interaction of multiple genes on different locations of chromosomes (strands of DNA that carry genetic information). The large variations of skin pigmentation among different populations are most likely due to natural selection. Depending on the geographical region, different selective pressures, such as vitamin D synthesis, nutrient breakdown, and photoprotection

from UV radiation, would change the amount of melanin produced in the body. Researchers have found that although decreased melanin levels have increased risk for skin cancer, most cases do not take effect until later in life and seldom cause death; thus, they have less of an influence on reproductive success.

Melanin and UV Radiation

In the skin, melanin functions as a filter for UV radiation by means of absorbing and scattering the electromagnetic radiation produced by the sun. The amount of protection is dependent on the amount of UV radiation that is able to pass through the earth's atmosphere (e.g., clouds, ozone, dust particles) to reach the body surface along with the location and density of melanin in the skin. Thus, deeply melanized skin provides protection against UV radiation, which is the primary cause of skin cancer. With ultraviolet-B (UVB) radiation causing sunburns that damage sweat glands, immediate negative effects on thermoregulation occur. Thus, the high density of melanin in darker skin is able to provide enhanced photoprotection along with more efficient recovery from growth inhibitory effects of UVB exposure. In addition, melanin has the free radical ability to absorb any carcinogenic or toxic compounds produced by photochemical reactions.

One of the benefits of UV radiation is its involvement in the synthesis of vitamin D. Because vitamin D is necessary for uptake of calcium and phosphate minerals from the intestines, it is vital for normal bone metabolism and skeletal growth along with nerve and muscle functioning. So long as humans are exposed to sufficient sunlight, UV photons are able to synthesize pre-vitamin D that is subsequently transformed into vitamin D at body temperature. Melanin has the ability to block the absorption of UV light that is needed to make vitamin D. Lighter skinned humans with low to moderate levels of melanin in their skin absorb more UV light; thus, they are able to synthesize more vitamin D. These individuals are at higher risk for developing skin cancer, especially when residing in areas of high UV radiation such as near the equator. On the other hand, there are also people who live in northern regions with low annual UV exposure. These individuals are at risk for having a vitamin D deficiency and must make sure that they compensate by ingesting enough vitamin D in their diets to be absorbed by their intestines. A deficiency

of this vitamin may cause bone disorders such as rickets (bowed bones and inflamed joints), osteomalacia (softening of bones), and osteoporosis (reduction in quantity of bone tissue). These may lead to immobilization, bone deformities, or even death.

Another molecule that is affected by UV light is folate. The photosensitivity of the folate molecule leads to complications because it is readily degraded by UV light. Folate is produced in the body from folic acid, an essential nutrient involved in nucleotide (building blocks of DNA and RNA) formation, and has been found to play crucial roles in red blood cell and bone marrow development. Defective and deficient folate levels have been linked to spermatogenesis (production of sperm) and various neural tube defects during embryo development. Thus, to inhibit the breakdown of folate, humans have adapted by increasing melanin formation in the skin to enhance reproductive success.

Within the eye, the color of the iris varies among humans and is dependent on the amount of brown or black pigment and the scattering of light caused by the tissue of the iris. For example, in some forms of albinism, the pupil appears to be red because there is no melanin pigment to absorb light, thereby causing the light to reflect off the blood vessels in the back of the eye. Furthermore, similar to the reason why the sky is blue and not black as in outer space, blue-eyed individuals are due to light scattering off the iris tissue.

Melanin also determines hair color. Near the base of the hair follicle, the bulb matrix contains melanocytes that produce and transfer melanin to keratinocytes in the outer portion of the hair follicle. Depending on the type of melanin and the amount of brown, black, and red pigment, various shades of hair color can be produced.

Skin Coloration

Skin color is determined by a number of factors, including genetic makeup, hormone levels, carotene levels, and amount of sun exposure. Depending on the location of pigments and the amount of sunlight reaching the human skin, absorbed UV light not only darkens melanin pigments but also stimulates melanin production.

In addition, the reddish tone that is often visible when a human blushes or is angry is caused by an increase in blood flow through the skin, whereas a

pale color in the skin is evident from decreased blood flow that occurs during a heart attack. Furthermore, cyanosis or decreased oxygen blood levels cause a dark bluish or purplish coloration of the skin.

During pregnancy, melanin production is affected by the hormones estrogen and melanocyte-stimulating hormone (MSH). The MSH is able to darken the skin by binding to receptors on melanocytes to stimulate melanin production. This is the reason for the darkening of the nipples, areolae (bumpy region surrounding the nipple), and genitalia.

Lastly, a yellow pigment called carotene is a good source of vitamin A and can be found in plants such as carrots. Because carotene is a fat-soluble compound, excess amounts accumulate in the epidermis and fat cells, causing the skin to develop a yellowish color.

Diseases and Complications

Some people inherit specific genes that cause them to be unable to produce tyrosinase, a necessary enzyme for melanin production. This condition, known as albinism, causes little or no production of melanin pigment in these people's eyes, skin, and hair. Aside from risk of isolation and vision problems, so long as sun-protective methods are used, albinos live normal life spans. This is clearly visible when looking at the Hopi Indian tribe. It has been suggested that the extremely high rate of albinism in this tribe, 1 in 200 people, is due to a mating advantage that is favorable and selected for "culturally." Albinism is a recessive trait that occurs in 1 in 17,000 people in the United States. Other diseases, such as Addison's, cause increased pigmentation by increasing the secretion of adrenocorticotrophic hormone and MSH.

Because skin cancer is the most common of all cancers, awareness of skin protection methods has become extremely important. The majority of cases with skin cancer are attributed to UV radiation from the sun. Thus, the people with the highest risk are those who are fair-skinned and live in areas of the world where high amounts of UV radiation penetrate the earth.

The most frequent type of skin cancer is basal cell carcinoma. Fortunately, this type rarely metastasizes (spreads to other areas of the body) and can be cured by radiation or removal. Squamous cell carcinoma is more life threatening because it may metastasize, but it usually remains a localized keratinized tumor (a swelling or growth) in the epidermis. Last, although

malignant melanoma is a less common form of skin cancer, it often arises from melanocytes that are within moles and may become life threatening. Although higher melanin skin levels lower the risk of skin cancer, they still occur in all skin colors around the world. The most effective means of preventing sunburn and skin cancer is by limiting sun exposure and using effective sunscreens that block both UVA and UVB radiation.

The fields of medicine and anthropology have made great strides toward uncovering our evolutionary past. Melanin plays a vital role, whether directly or indirectly, in human health, history, and evolution. Depending on the particular geographical region, selective pressures have allowed humans to adapt so as to enhance their reproductive success. With technological improvements, the scientific world will continue to make discoveries to improve our understanding of melanin and its effects on the human body. For example, recent studies have shown correlations between multiple sclerosis and skin pigmentation. Further research will enable our health care system to have a better understanding of factors affecting these diseases that will enable improved preventive measures and more effective treatments. With increased knowledge, dedication, and opportunity, new cures for these diseases and cancers might develop in the near future.

Memes are items that evolve in an evolutionary process covering the social and cultural domain only. They are sociocultural analogues to genes or viruses.

The idea of a cultural item that evolves the same way as biological entities do goes back at least to Herbert Spencer. The notion that culture is passed on like a disease also goes back to the same period. But both metaphors have usually been treated as just that—suggestive similes of no serious import. The first person to take the evolutionary idea seriously was zoologist Richard Semon, a student of Ernst Haeckel, in his 1904 book *Die Mneme* (published in English as *The Mneme* in 1924). Semon’s mneme idea was not limited to culture; it also included any impression left on an organism by external factors (*Engramm*), that is, acquired inheritance.

The differentiation of cultural evolution from biological evolution appeared in 1965 in the work of Donald T. Campbell, who influenced Karl Popper to develop an evolutionary epistemology in 1972, and in various other authors, including Julian Huxley in 1957 and Stephen Toulmin in 1972. In 1981, C. J. Lumsden and E. O. Wilson and proposed the notion of a “cultorgen” (culture–gene) as the target of evolution in culture. A number of other “dual inheritance” models of culture have been proposed. But the modern fascination with the idea of a meme derives mainly from the writings of the theorist who coined the term, Richard Dawkins.

Dawkins developed a generalized theory of evolutionary processes independent of the physical substrate in which they were realized and termed it *universal Darwinism*. The relevant entities of all evolutionary processes included what Dawkins called a replicator, an entity that copies itself according to three criteria,

namely that it is fecund, it is high fidelity, and it is long-lived. “Longevity, fecundity, and fidelity” is the slogan of this new revolution. Dawkins’s view of evolution has come to be known as the gene’s eye view.

Replicators in biology are DNA based, Dawkins said. But in cultural evolution, they are something else—*memes*, a term coined to be similar to *gene*, with which it was grouped as a replicator. Dawkins used two analogies for memes. One was that memes, like genes, are the things that evolve, setting up a problem as to the contents of memes. The other was that memes are mobile hereditary elements like viruses, taking over the resources of a host brain the same way as a virus subverts the cellular machinery of its hosts to replicate.

Advocates of the memes-as-germs approach, as one might call it, tend to focus on the epidemiological aspect of culture. In this regard, this approach is closely allied to the anthropological conception of diffusion. Advocates of the memes-as-genes approach, on the contrary, focus on the selectionist aspects of memes, their fitness, and so forth. There are strong advocates and critics of both approaches.

Because the notion of a meme is tied into the universal Darwinism of Dawkins, and the consequent ontology of phenotype analogues (*vehicles* in Dawkins’s terms, *interactors* in Hull’s terms), two questions that have engendered considerable debate arise. First, what is a meme? Second, what is the phenotype of a meme? Answers have included that memes are neural structures or activated neural constellations and that they are artifacts, behaviors, or the subject of selection pressures in cultural transmission. Examples have included dress practices, snatches of tunes, phrases, pottery styles, and architectural styles. But it remains unclear whether these are the things that replicate or the things that express what is replicated. Some hold that memes are the physical things that are recreated, the practices, or the artifacts. Others hold them to be the ideas or symbolic representations that are passed on and that cause the external behaviors and products of behavior. In short, in the former view, memes are concrete things that get reproduced; in the latter view, memes are abstract things that result in concrete phenotypic behaviors and products. A “multilevel selection” approach, as may be found in modern biological accounts, applied to memes suggests that memes, as selective targets, may be replicators at any level of the hierarchy of the evolutionary domain, and so memes may be both within heads and between them.

A further consideration is whether cultural evolution needs to be strongly selectionist. This reflects in part the motivations of those who find memes interesting because selection is such a powerful explanation of complex dynamic systems—a “universal acid,” as Dennett described it in 1995—and also the traditional conflation between Darwinism and natural selection. Strongly selectionist processes run the risk, in a fitness landscape that is not smooth, of being “marooned” on a lower than optimal fitness peak. In cases where culture is regarded to have made considerable progress or to have become especially well adapted, strong selectionist accounts ironically cannot account for this on realistic assumptions about fitness landscapes. A good example is in science, which David Hull analyzed as a memetic evolutionary process in 1988 in the most detailed study to date. Strong selectionism cannot explain why a science progresses if the entire discipline is regarded as a single deme.

Another issue is what counts as the selective regime or environment of a meme. Some, such as Susan Blackmore, think that human brains are the selective environment and that memes take over the behavior of the host the same way as some parasites control the behavior of their biological hosts. In fact, Blackmore, in her 1999 book, maintained that there is no “ego” apart from the controlling memes. Others hold that the society is the ecology, and that the culture is the ecological relations within it, in an analogy between ecosystems and ecotypical trophic webs. A consensual resolution on these issues has not yet been reached.

MESOLITHIC CULTURES

The Mesolithic epoch, or the “middle stone age,” nowadays is interpreted as a Holocene stage of hunter-gatherer society development. Two opposing interpretations of historical status of the Mesolithic epoch have competed in archaeological science during the past century. Many researchers regard the Mesolithic as an important phase of human history and as a specific archaeological epoch characterized by a set of features in tool production, livelihood, economy, social organization, art, ideology, and so forth. Another group of Early Holocene settlement investigators regard the Mesolithic as a period of transition from a society of Pleistocene hunter-gatherers to mid-Holocene communities of early farmers and cattle breeders.

Although the term *Mesolithic* had been proposed as early as 1874 by M. Torell, the taxonomic importance and historical essence of this period is discussed in contemporary archaeology. The term *Epipaleolithic* is often applied to this period by those scientists who believe that no principal changes in culture had occurred since the 17 million BC, that is, since the beginning of deglaciation. Another group of archaeologists prefers to use the term *nonceramic* or *preceramic Neolithic*, thereby stressing that the process of

productive economy formation had already begun by the beginning of the Holocene. In the course of the discussion about the historical status of the Mesolithic period and about the most suitable term for it, a series of criteria for the Mesolithic epoch has been put forward.

Mesolithic as Historical Epoch: Diversity of Criteria

Technological Criteria

The most striking features of the Mesolithic flint industry were as follows:

- Extreme microlithization of tools, blades, flakes, nuclei, and debitage
- Substantial decrease of percentage of artifacts with traces of secondary processing (e.g., retouch, truncation, chipping) and intensive use of chips (mostly prismatic microblades and blades) without further processing
- Absolute domination of the insert-based tool production technique that actively applied inserts of geometric forms (e.g., trapezes, triangles, segments), opening the possibility of reuse and interchangeability of artifacts in different sorts of activity (e.g., hunting, butchering, gathering, tool making, clothes making, house building, household activities)
- Macrolithic forms (e.g., axes, tranchetes, adzes, bits) in wide distribution in boreal territories all over the world

Climatic Criteria

Traditionally, the Mesolithic is correlated with transition from the glacial period (Pleistocene) to the postglacial period (Holocene). Climate global changes were accompanied by transformation of fauna (replacement of big gregarious animals by small nongregarious species) and flora that resulted in formation of contemporary kinds and types of geographic landscapes and zones. Such transformation of natural habitat had caused reformation of the human mode of life and way of cultural adaptation.

Economic Criteria

Differential development of various spheres of a hunter-gatherers economy in direct connection with peculiarities of a local environment was displayed strikingly during the Mesolithic times. At the same

time, it was not only an epoch of nonspecialized hunting of nongregarious animals but also a period when the necessary background for the transition to a productive economy had been formed. In some regions, one can trace the existence of its first developed forms (mainly Fertile Crescent mainly). In others, only specific forms of animal juveniles treating known as “live food supply” and/or simple harvesting were practiced (e.g., Black and Mediterranean Sea region).

Another specific feature of the Mesolithic economy also connected with the necessity to improve the population subsistence base was intensification of the gathering of salt and sweet water mollusks. It is traced to the origin of specific kinds of settlements known as *kokkenmeddings* found in Northern Europe, the British Isles, the Pyrenean peninsula, the Apennines, Crimea, and other seashore areas.

Substantial development of fishing was also connected with the necessity to secure a food supply. It was accompanied by the invention of special means (e.g., wicker nets, fishhooks, rafts, boats) and sometimes provided bases for a rather settled mode of life.

Social criteria include two phenomena traced independently to different parts of the world and different geographic regions:

- Disintegration of numerous communities of the Ice Age and growth of economic importance and social independence of small mobile groups of hunter-gatherers, as reflected in the absolute domination of short-term sites without dwellings and other household construction
- Origin of primitive forms of tribal organization, as reflected in the appearance of collective burials

Other Features

Representatives of different approaches to Mesolithic culture interpretation often mention other features that defined historical specificity of this period. One of the most important among them is the invention of series of means of transport caused by the necessity to secure movement of population groups searching for new foraging territories (e.g., canoes, rafts, skis, sleighs).

The development of an exchange network resulting from the development of transportation means also is regarded as a peculiar characteristic of the Mesolithic.

The wide distribution of stone vessels for bone overcooking and for preparation of herbal tea and decoction, and possibly also meat stock, is traced to most regions of Europe. Such a practice was aimed at efficiency of food procurement maximization by extreme use of products.

Sometimes the origin of Borean (Nostratic) language unity is mentioned. Its further development is traced to the origin of ancestors of Indo-European, Ural, and Semitic languages.

Extreme rock art schematization reflected general symbolization of the outer world, and abstraction of mental activity of hunter-gatherers could be regarded as another Mesolithic culture feature.

Periodization and Chronological Frameworks of the Mesolithic

Two kinds of the Mesolithic periodization are usually used in contemporary archaeology. One of them divides the Mesolithic into two stages:

- Early stage (10,300–8,200 years BP)
- Late stage (8,200–7,000 years BP)

During the first half of the 20th century, these stages were called Azilian and Tardenoisian, respectively. Nowadays, such names are applied to local cultures distributed on the territory of contemporary France and neighboring regions.

During the past decade, one could trace the growth in popularity of the ecological approach of the Mesolithic interpretation and, as a result, a shift toward a preference for another variant of the Mesolithic period, according to which Holocene climatic phases correlate with phases of culture development:

- Preboreal phase (10,300–9,700 years BP)
- Boreal phase (9,700–8,200 years BP)
- Atlantic phase (8,200–7,000 years BP)

At the same time, it needs to be stressed that a series of Mesolithic settlements, in their flint knapping technology sites, are dated by final stages of final glacial times. The earliest examples are correlated with Allerød warming (13 million years BP), and many Dryas III settlements in the southern part of Eastern and Western Europe are interpreted as Mesolithic ones. On the other hand, a series of dates

obtained for Mesolithic sites in the Boreal zone of Northern Europe are dated less than 7 million years BP.

The best explanation of such variability of Mesolithic period dating in different geographical zones was proposed by proponents of an ecological version of the Mesolithic interpretation. According to this version, the Mesolithic is regarded as an objective and reasonable response of hunter-gatherer societies to climatic and landscape changes that occurred as a result of the last deglaciation. So far as this process fit geographic regularities, it began at southern regions much earlier than at northern territories and caused further nonsynchronicity of the Mesolithic culture's existence in different latitudes. Landscape capacity to satisfy subsistence needs of hunter-gatherers defined the upper chronological frame of the Mesolithic. Inhabitants of southern regions, whose source base was explored extensively, and often nonrationally, for a long period of time, needed to transform their culture earlier than did populations of newly settled northern territories.

Local Diversity of Mesolithic Cultures

Although the Mesolithic is characterized by general features, their peculiar displays and relative importance in different regions can vary greatly.

The southern regions of Western and Eastern Europe give us brilliant examples of flint knapping technique improvements and standardization in the genre of prismatic chipping, artifact micritization, reduction of chip secondary treatment, and domination of the insert (often of geometric forms) technique of tool making. In these regions are scarce complex settlements (except those in caves) and an absolute predominance of short-term sites without dwellings, and household objects testify to a highly mobile mode of life and a high grade of dispersion of Mesolithic population specializing in small group or individual hunting of nongregarious game (e.g., red deer, auroch, wild boar) and birds.

The northern territories of Europe illustrate a Boreal variant of the Mesolithic culture connected with a wide distribution of fishing practices and gathering of plants, nuts, mollusks, and the like. Special types of settlements on platforms and so-called kokkenmeddings reflect peculiarities of such a subsistence system caused by natural habitat features. Elk and red deer are represented among hunting species, and their importance in human life is also reflected in

objects of portable art. Tool kits contain many tools for wood processing as well as many wooden and bone artifacts. Mollusk shells and fish carcasses also were used in household activities.

The Middle East displays a very different mode of Mesolithic cultures development based on the origin of early farming and cattle breeding as early as 11,000 years BP. The introduction of wheat, barley, and rye, as well as the domestication of sheep, goats, cows, and pigs, took place here. The creation of complex settlements with mono- and multicameral rectangular and circular dwellings on stone foundations and weaved walls covered by clay was inherent to early agriculturists of the Fertile Crescent. A lot of so-called "luxurious" (or simply rare) artifacts made of steatite, volcanic glass, marble, porphyry, resin, and the like have been found at such settlements. They were imported from remote northern and southern territories and indicated a high level of exchange system development.

In North America, after the last glaciation (post-Wisconsin time or Early Holocene), transformation of local culture was not connected with migrations from Asia for the first time in the history of American populations. The origin of the Plano culture, based on specialized hunting of bison, is regarded as an inner process caused by previous phases of culture development in a transformed postglacial landscape. During the Mesolithic, all places suitable for human life near big river flows and in foothills were inhabited. This resulted from the necessity of permanent changes of settlement places in search of game. Hunting weapons were based on a specific kind of grooved inserts called "plano points" and testify to a high level of tool production development. Wide possibilities of social culture, daily life, and ideology of Mesolithic populations of North America are opened by ethnographic analogies based on interdisciplinary studies of Indian populations.

MESOPOTAMIAN CIVILIZATION

Mesopotamia is the ancient land between the Tigris and Euphrates rivers. It covers modern day Iraq and parts of Iran, Turkey, Syria, Lebanon, and Israel. Mesopotamian civilizations were the first in history to exist in well-populated and fixed settlements. As settlements became larger and more organized, they progressed politically and socially into city-states. They developed irrigation methods and invented the wheel and the plow. After they developed the first written language, economic transactions and legal codes were kept. Mesopotamian literature was recorded. Great architectural structures were built. In time, empires, kings, and innovative military establishments emerged. These advancements, along with scientific, mathematical, and communal ceremonies, are the legacies of the great Mesopotamian civilizations.

Mesopotamia was the heartland of emerging nations and empires that would control the Near East for centuries. Mesopotamia is a general name for a number of diverse ethnic groups that contributed to the culture of the region. The most well-known Mesopotamian civilizations include the Sumerians, Babylonians, and Assyrians. Other cultural groups may have been key players on the Mesopotamian stage, but none was as influential as these groups.

The Sumerians captured the region beginning in the Early Dynastic period (ca. 2900 BC) and ending with the Third Dynasty of Ur (ca. 2004 BC). Over these years, Sumerians developed the first writing system and created epic literature. They invented the wheel, the plow, and the earliest known irrigation methods, enabling an otherwise unstable agricultural environment to prosper as Sumerian settlements grew into the world's first political city-states. Under an Akkadian Empire (ca. 2334–2193 BC), this land of independent city-states consumed the entire Mesopotamian.

Babylon was located in the southern part of modern Iraq, between Baghdad and the Persian Gulf. At its cultural height (1900 BC to 1595 BC), the Babylonian civilization unified its Mesopotamia region. Many adored Babylonian civilization because it was a melting pot of many ethnic groups. Even the emperors and barbarians who battled for control of Babylon preferred assimilation into its dynamic cultural heritage.

Assur lay to the north in the Upper Tigris Valley and around the ancient city of Nineveh. Assyrians were a fierce cultural group, and the Assyrian empire reigned during a time of intense warfare. Assyrian control constantly expanded and receded in its quest for complete domination of Mesopotamia. At one time, the empire had expanded from Egypt, far to the east, to Iran in the west. At another time, Assyrian control receded to near extinction. The civilization reached its zenith from 910 BC to circa 610 BC but would eventually fall to a renewed Babylonian military.

Mesopotamia Begins in Sumer

The first inhabitants of this Mesopotamian region settled in a broad range of foothills that surrounded the Mesopotamian plains known as the Fertile Crescent. The region ran from central Palestine, north to Syria and eastern Asia Minor, and extending eastward to northern Iraq and Iran. During the historic periods known as the Mesolithic and Neolithic periods (ca. 9000–5800 BC), the people of the Fertile Crescent began to abandon a lifestyle where hunting and food gathering prevailed and entered a period of food production. They settled into farming and herding communities. As they became skilled in animal husbandry and farming, they were able to produce more food and the population in this region soared.

Although the villages in the Fertile Crescent became more sophisticated and sedentary, the people migrated southward, into the Mesopotamian Plains, between 6000 and 5000 BC. Some families and clans may have migrated to escape excessive population and overcrowding. Others may have left due to social or political discontent. Still other evidence suggests that a great flood may have wiped out the shores surrounding the Black Sea and that many settlers may have been refugees of this huge natural disaster.

The earliest Mesopotamians existed in a variable climate with a geography that included deserts, mountains, and river plains. Although northern Mesopotamia had adequate rainfall for successful agriculture, the remaining regions required irrigation and skilled control of the Tigris and Euphrates rivers. Southern Mesopotamian settlements may have begun using irrigation principles as early as 5000 BC. Their ability to irrigate allowed growth in settlement populations, which then created a need for organized communal work and complex hierarchical social structures.

During these years, an immigrant group of settlers known as the Sumerians settled into the Mesopotamian region. Sumerians were a very influential culture. Future peoples in this region preserved aspects of the Sumerian political and social customs as well as Sumerian literature and artistic style. Sumerians created the first wheel and the plow. Their skilled irrigation methods enabled an increase in food production. Sumerians rapidly turned agricultural communities into urban developments as they built the first cities. Sumerians also developed the writing system that enabled nobles and rulers to record economic transactions and legal decrees.

Sumerian city-states were independent of one another, and each was focused on controlling and supporting its farmlands and villages. The earliest city-states developed by the Sumerians were originally organized around a temple and a priesthood governed by an *en* ("high priest"). The *en* represented the local god and managed the temple lands that the people entrusted to work on them. As societies grew more complex, an *ensi* ("governor") emerged to manage civic affairs such as law and order, commerce, trade, and military efforts. In time, people would select a leader, called a *lugal* ("great man"), to rule during times of war and peril. The *lugal* managed all civil, military, and religious functions of the city. The office of *lugal* seemed to emerge at a time when

defense walls were first constructed. As war became a constant threat, rulers became kings who would remain in power for their lifetimes, passing rule onto their sons as successors to their thrones. As a state of dynasties took root, kings and royal families emerged.

One of the most elaborate and impressive architectural structures of this time was the *ziggurat*, a multi-level platformed temple of worship. The oldest ziggurat was unearthed in the city-state of Ur. C. Leonard Wooley was the archaeologist who discovered most of what we know about this ancient city. He also uncovered ancient burial tombs that included not only the deceased but also physical possessions and domestic servants. Experts believe that the burial tomb included everything that the Sumerians believed would be needed for a comfortable afterlife.

By the second half of the third millennium, the Semitic-speaking people were a significant element in northern Mesopotamia, also known as Akkad. The most notable kings of the time were Sargon of Akkad and his grandson, Naram-Sin. They enslaved Sumerian city-states and achieved control of the trade routes from the Persian Gulf to the Mediterranean, achieving for the first time a unified Mesopotamian region. Sumerian culture and cuneiform were retained, but Akkadian tongue became the dominant language in Mesopotamia. The empire of Sargon and his grandson reigned for nearly a century. But the Akkadian empire would then fall, leaving its legacy of imperialistic expansion.

The Third Dynasty of Ur came into power circa 2112 to 2004 BC. This Sumerian dynasty governed most of Mesopotamia and southwestern Iran. Its founder, Ur-Nammu, wrote the oldest known collection of laws, intended to protect the economically and politically weak. As this dynasty fell to pressure from the Amorites, another migration of Semites who originated west of the Euphrates, central imperial control disappeared.

Babylonian Culture

According to scholars, the years following the Third Dynasty of Ur are called the Old Babylonian period (2000–1400 BC). For many years, Mesopotamia was disunited, with independent city-states frequently engaging in disputes and wars with its neighbors. This time of intense conflict was a time of great political opportunity for the most powerful men in Mesopotamia. The most successful leaders to

establish dynasties were Amorites, who spoke Akkadian, and Elamites, who spoke a tongue unrelated to any others in the region. The Akkadian speakers settled a strong state in the city of Assur. When Ur fell to the Elamites, Assyrians became a leading political–military force. In 1813 BC, Shamshi-Adad overthrew Assur and established a new dynasty there. Because Shamshi-Adad's troops were consumed by military expeditions, he avoided attacks on the strong city-state of Babylon that lay southeast of Assur. The attacks Shamshi-Adad did launch were relatively small scale and ceased after his death in 1781 BC. His successor was then squashed by a Babylonian army led by the sixth king of an Amorite dynasty that had established itself circa 1850 BC.

This widely respected and feared king was known as Hammurabi and lived in Babylonia. Hammurabi wrote the most famous laws of the time, known as the Code of Hammurabi, which embraced and proclaimed an “eye for an eye” discipline. Hammurabi also became the first king since Sargon of Akkad to unite the entire Mesopotamia land, stretching from the Persian Gulf to the Syrian border and the Armenian foothills. He was a skilled military leader and conqueror. Under his administration, trade flourished. He attended to domestic and economic issues while promoting literature, the arts, and science.

However, the peaceful times he created diminished shortly after his death in 1750 BC. What followed was a time of military conflict and strikes for the captured territories that wanted to break from Hammurabi's Babylonia. Eventually, the city of Babylonia fell to the Kassite nobles, who took the city in 1400 BC. They were so impressed with the refined culture that they became assimilated into the Babylonian way, abandoning their native tongue for the Akkadian dialect of the Babylonians. In fact, the Kassites stabilized the region for more than four centuries, the longest period in Babylonian history.

Great military innovations developed during the Old Babylonian period. The horse was domesticated. After the wheel was redesigned with spokes instead of a solid surface, horses were harnessed to chariots to enable military attacks en masse. The bow was also redesigned to fly faster and farther. These changes were implemented, and large-scale military action was possible.

Although Mesopotamians were famous for building elaborate palaces, the most impressive palace belonged to King Nebuchadnezzar II of Babylon

(604–562 BC). Although no archaeological evidence or other physical remains have ever been found, this palace is said to contain the legendary Hanging Gardens of Babylon, built to please one of Nebuchadnezzar's wives who was homesick for her mountainous Iranian homeland that was lush with foliage.

The Assyrians

In 1365 BC, during a time that some modern scholars call the Middle Assyrian period, the Assyrians launched their first major front in the northwest from the border of Hatti, through Armenia, and to the Zagros Mountains. In a series of small-scale attacks, the Assyrians use their newfound military innovations to take human captives, horses, and other war booty. The Assyrians continued a second major front to seize Babylon and placed it under the rule of a monarch, Tukulti-Ninurta I, who reigned from 1244 to 1208 BC. Although this victory filled the Assyrians with great pride and satisfaction, the great Babylonian nobles would rebel. In 1165, a strong Elamite king would lay permanent claim to the great city.

In the next tactical front, the Assyrians fought relentlessly from Syria to the Mediterranean Sea. In the most amazing gain during this period of empirical expansion, King Tiglathpileser I took control of the Mesopotamian region from the Mediterranean Sea to Babylon. He was assassinated in 1077, and because his successors could not hold together this vast land, in time the Assyrian empire shrank until only Assur and Nineveh remained. It lay dormant until reaching its height during the Neo-Assyrian Empire circa 911 to 612 BC. This was a time when the Assyrian army became a highly skilled machine. Merciless warrior kings launched repeated military campaigns and attained impressive imperialistic growth. Assyrian conquest extended across the Near East and made Nineveh one of the richest cities in the Ancient World.

The greed of the Assyrians would be their demise. Nineveh and the Assyrian control would soon fall to the Babylonians and Medes. At this time, the splendor of the three greatest cultures of Mesopotamian civilizations would become legend. Their great contributions to the time and to world history were a finality. For the next several hundred years, the land would fall to many new tribes, new empires, and other dynasties, but none would be as influential as those of the Sumerians, Babylonians, and Assyrians.

From 539 to 331 BC, Persians saw Aramaic replace the long-standing Akkadian language. In 331 BC, Alexander the Great would take the region and make Babylon the capital of his empire. The Parthians, and then the Sassians, would later rule the land. When Islamic control began in 651 AD, a time and a culture known as ancient Mesopotamia ended.

METALLURGY

Metallurgy deals with the study of metals and their ores as well as the processes for extracting, purifying, and alloying metals and production of metal objects. Humans have practiced the use of metals in various forms for nearly 9,000 years, beginning with copper during the eighth millennium BC. Cross-culturally, the processes involved with working metals are often shrouded with superstition and magical beliefs. Although the production of some metals requires sophisticated technology, there is virtually no culture in the world today that does not use at least some metal objects.

Common metals employed throughout the world include copper, silver, gold, lead, iron, tin, zinc, and arsenic. Of these, the first three occur in relatively pure or “native” form, whereas the others occur only in chemical compounds from which they must be extracted before use. Common metallic compounds from which metals are extracted include metallic

salts, phosphates, and carbonates. Although some of these compounds exist in surface deposits, most metals and metal ores are mined.

The earliest documented uses of metals occurred in Iran and Anatolia during the eighth millennium BC in the Old World and circa 1500 BC in the Andes Mountains of the New World. In both cases, the first metals used were relatively pure forms of copper mined with stone and antler tools and processed with simple cold hammering techniques.

Later metal workers developed uses for alloys, that is, mixtures of a metal with one or more additional elements, often metals. Alloys are often favored because they offer technical properties that are not present in constituent elements. Common alloys include bronze (copper and either tin or arsenic), brass (copper and zinc), and pewter (tin, copper, antimony, and sometimes lead). Steel, one of the hardest metals, is made from alloying iron with carbon and sometimes other components such as manganese, chromium, and nickel.

The so-called “precious metals”—gold, silver, and platinum—are relatively rare and therefore expensive. Gold and silver especially have a long history of use as jewelry and other ornaments. Although they are obtainable in pure forms, they are often used as alloys to reduce the cost of objects and to create desirable characteristics of hardness and color.

Mines are usually used to extract metal ores from the earth if veins of ore are not available on the surface. However, native gold, called “placer gold,” occurs in alluvial deposits and can be collected by panning or washing. In most cultures, mining is considered a relatively undesirable job, even where the potential economic benefits are lucrative. This is due in part to the perceived, and often real, danger of underground mining. In addition to the apparent threats from explosives, heavy equipment, and possible cave-ins of mine shafts, miners face unseen dangers in the form of noxious gasses and airborne compounds, such as silica, that can damage the lungs.

Many cultures also maintain beliefs about supernatural beings that can influence the lives of miners. One such being is the Tio of Andean mines. Tio takes the form of a devil, often red with pointed horns, and inhabits a shrine located within the mine tunnels. Andean miners make offerings of cigarettes, coca leaves, and alcohol to propitiate Tio, who is asked to reciprocate in the form of pure ores of high value.

Traditionally, mining has been carried out by men, but women and children often participate by working mine tailings and panning. When mine work is part of compulsory service, families often accompany male miners to provide food, clothing, and other needs for the miners. Children are sometimes preferred workers in mines because their smaller size makes it easy for them to move around in small mine tunnels and their small fingers are thought to be agile at separating ore from other rocks and debris. In most countries, the use of children's labor in metal extraction is officially discouraged, but small subcontractors often continue to employ their illegal labor.

Smelting involves heating metal ore to a high temperature to remove unwanted material from the ore. To achieve this, the ore must be melted in a ceramic crucible. At high enough temperatures normally achievable only in a closed furnace, the waste material (or *gangue*) will melt out and be left behind as slag. The long hours involved in smelting and the enormous requirements for fuel and air circulation, often by the use of bellows, mean that smelting is usually a group activity. Men are most often directly involved with smelting, but women and children may help to provide fuel to heat the furnace. Perhaps because the purification process happens out of sight, in the heat of the furnace, it has often been associated with ritual and magic. For example, worship of the Yoruba orisha Ogun, the deity of iron, is closely associated with male smelting activities.

Whether as native metal or as alloy, metals may be worked and formed into objects in a variety of ways. Soft metals, such as copper and gold, may be hammered cold, representing the earliest metal working techniques. Smithing uses the heat of a forge or hearth to make metals more pliable so that they can be worked into shape with a hammer and anvil. Blacksmithing, the working of iron and steel, is accompanied by both skill and ritual knowledge that can require long apprenticeships to obtain. This is the case with Japanese master sword makers, who use elaborate techniques of folding, annealing, and tempering to produce blades that are strong, flexible, and beautiful. Casting involves the heating of metal to a liquid state and pouring it into a mold. Bronze, one of the first metals to be cast, was so widely spread in the Old World that the periods characterized by its appearance are referred to as the Bronze Age. Metals may also be cut or ground to produce desired shapes.

The use of metals in pure or alloyed form varies among cultures and depends in part on available technology and intended uses. Common uses for metals include tools, weapons, personal adornment, coinage, art, and symbols of state (e.g., medals, crowns, scepters).

Mexico ranks among the world's most important locations of anthropologists and anthropological research. It was a center of crop domestication and village settlement and one of the few sites of primary state formation. It witnessed a rich and varied history of complex societies, including writing, urbanization, and class hierarchies. Study of the Spanish conquest and colonial transformations has provided crucial understandings of how apparently "local" peasant communities and other social formations form part of world capitalism. Much anthropological work on power and inequality has taken place about and within Mexico. Finally, Mexico has provided the setting for key studies of cities and migration, and its contemporary politics contributes significantly to our understanding of indigenous peoples and social movements under the conditions of globalization.

Mexico includes most of the cultural region called Mesoamerica. Mesoamerica extends into the northern

half of Central America. On the other hand, the arid north of Mexico falls outside of Mesoamerica proper, being a transitional cultural region with affinities to both the southwestern United States and Mesoamerica. These cultural boundaries, however, are not to be taken as hermetically sealed; during the pre-Columbian era, there was considerable interaction between Mesoamerica and Central America and even South America and North America. Within Mesoamerica, the Maya region in the south and the central Mexican highlands constitute strong foci, but there are other regional cultures due to the rugged and complex topography, so internal differences and interactions are also significant.

Mesoamerica during the post-Columbian period had involvements of even a wider scale, so that it must be viewed in terms of combined and uneven relationships with Europe (via Spain) and the United States. Indeed, emerging from colonial New Spain and then explicitly with Mexican nationhood in 1821, our unit of analysis shifts from a culture region approach (Mesoamerica) to one of a political entity with cultural consequences (Mexico). One cannot speak of the Mexican nation and its people as culturally uniform—indeed, Mexico's linguistic, cultural, and regional variations are enormous—but recent work has addressed precisely the consolidation of the Mexican state as a cultural framework for more specific local and regional phenomena.

There is a long history of written records from Mesoamerica, but deliberate collection and analysis of knowledge about culture (anthropology, we might say) may be said to have begun after the Spanish conquest among literate indigenous Mexicans and European priests looking back on pre-Columbian societies and their practices. A notable instance was the project supervised by Father Bernardino de Sahagun, in which *Nahua* (central Mexican or "Mexica") elites provided to the priest a vast body of information about the Aztec empire and its constituent city-states. Contemporary scholars carefully reread these documents, identifying the Mexica and European elements and noting the agreements, conflicts, and reinterpretations involved in this early anthropological collaboration.

Later colonial accounts are less notable. By the 19th century, much knowledge was hidden in dusty archives and overgrown ruins. Early explorations in Mexico started to recognize an important point, namely that the civilizations of the New World

resembled key Old World civilizations in many ways but did not follow exactly the same sequences or have identical traits. This sparked the vital field of Mesoamerican archaeology, which continues to the present. Among its highlights is the study of the domestication of corn, which not only is an important crop but also presents unusual challenges in its reconstruction. The field includes seminal studies of sedentism and the formation of village societies in Tehuacan and Oaxaca and then the emergence of stratified societies in the Olmec and later central Mexican and Maya areas. Long-term longitudinal studies of changing settlement patterns have been particularly influential in Mesoamerican archaeology, addressing fundamental questions such as the relationship between irrigation and the centralization of power. Recent breakthroughs in reading pre-Columbian Maya writing has resulted in a much richer understanding of political dynamics in Maya city-states, and this in turn has provided a more processual approach to the cultural evolution of power that previously had been dominated by stage approaches. Finally, important intellectual linkages between cultural anthropology and archaeology developed in Mexico, notably a shared interest in agrarian class societies and relations among peasants and elites as well as among countryside and cities.

To understand the ethnohistory and cultural anthropology of Mexico, it is helpful to distinguish work done by Mexican anthropologists (including exiled Spaniards) from work done by foreign anthropologists, mostly from the United States (realizing, of course, that the two sets of anthropologists were constantly sharing ideas and findings). Mexican anthropology developed in relation to the Mexican state (sometimes in support, sometimes in opposition) and its project of unifying the varied cultures and regions of the country. U.S. anthropologists, on the other hand, had a more globalizing project, taking Mexican cases as sources for theoretical arguments that extended beyond one country (reflecting, nevertheless, the subtle neocolonial relationship of Mexico with the colossus of the north).

Post-1910 revolutionary Mexican intellectuals turned to Mexico's indigenous past and present, abandoning the openly racist and pro-European perspectives that had existed previously. The pioneering Mexican anthropologist Manuel Gamio took as his agenda creating nationhood, as in the title of his principal book *Forjando patria*. The Mexican essence was

supposedly *mestizo*, that is, a mixture of European and indigenous ancestry and cultures. This encouraged the study of native Mexican cultures, especially the glories of past Mesoamerican civilizations, but only as antecedents for the future—the *mestizo* nation. The problem was that this treated the nonindigenous people of Mexico (who included among them the political and economic elite) as the ideal toward which the nation would evolve, whereas indigenous peoples were relegated to being a cultural resource for nationalists rather than living communities with identities and trajectories of their own. In this way, Mexican anthropology developed a close relationship with the central state, including a national school and museum of anthropology, two large employers (a national indigenous institute and an agency for anthropological and historical heritage management and scholarship), and a presence in school curricula from elementary schools to universities.

This approach was challenged starting in the late 1940s. Gonzalo Aguirre Beltrán argued that the

obstacle to Mexican modernity came not from indigenous peoples themselves but rather from persistent colonial relationships between *mestizo* regional elites and indigenous peoples that obstructed change. Ángel Palerm and Pedro Armillas (intellectuals exiled after the Spanish civil war) and Eric Wolf (a U.S. anthropologist who was also a European exile from the Nazis) went further, probing the long history of Mexican power and questioning the position of the Mexican *mestizos* as the carriers of modernity. They traced the continuity and transformations of central rule in Mexico from the Aztec era through Spanish colonialism to the rise of the 20th-century revolutionary elite. They linked seemingly backward Mexican institutions, such as the *haciendas* (great landed estates) and closed indigenous communities, to the most advanced dynamics of the world economy. Intellectually, they shifted the focus of Mexican anthropology from cultural traits to class relations, raising peasant studies to the fore. Palerm, Beltrán, and others also labored valiantly to improve the quality of Mexican

anthropological education, including greater knowledge of theory and more sophisticated field methods.

By the late 1960s, anthropologists, as part of the wider Mexican student movement for democracy and social justice, confronted the intimate relationship between Mexican anthropology and the Mexican state. Intellectually, this led to important, if sometimes arcane, debates between those who saw peasants as disappearing into the orthodox Marxist “working class” and those who saw the peasant–state–capital relationship as continuing to hold a vital role in the nation’s future. By the 1990s, the limitations of this work were visible. Poorly understood Marxist orthodoxy sometimes substituted for serious fieldwork. More important, indigenous peoples themselves demanded that they be taken seriously in cultural terms, not just as social classes. Radical social movements sprung up among indigenous peoples in Chiapas, Oaxaca, and elsewhere, simultaneously challenging capitalist globalization, the authoritarian Mexican state, and local race/class inequalities. Mexican and foreign anthropologists, by sympathy and necessity, reconsidered their frameworks, no longer contrasting but rather bringing together culture and political economy.

U.S. and other foreign anthropologists came to Mexico, often as romantic intellectual self-exiles from bourgeois societies seeking the culturally distinctive and exotic. This led, in the work of Robert Redfield, to the influential notion of folk culture, an integrated traditional local society and way of life. Other anthropologists focused on the most pre-Columbian features of indigenous Mexican cultures, often finding them in the esoterica of ritual performance. Yet as Oscar Lewis showed, the empirical basis for Redfield’s folk ideal was flawed, ignoring violent conflict and severe inequality in the Mexican countryside. Scholars began to follow Eric Wolf’s lead in tracing the connections between apparently non-European, traditional cultural practices and the European-focused capitalist world system. U.S. anthropologists, often interacting with Mexican scholars, then took Mexico as a key ground for debating issues of social change such as modernization theory and its critiques. Some of the best studies examined the economics of rituals in indigenous communities in terms of intracommunity and external relations of production and power. Recent work has converged with the social movement focus of contemporary Mexican anthropology.

Alongside this intellectual history, it is important to realize that Mexico itself has changed dramatically.

Four topics merit comment. First, the country has urbanized, and both U.S. and Mexican anthropologists followed displaced peasants and plantation workers into cities. Ethnographers demonstrated that the poor living in marginal areas of large cities had organized social patterns and were not anomic, socially isolated individuals. Likewise, huge industrial working classes emerged in Mexican domestic industries and increasingly in global export factories, many of them dedicated to the assembly of consumer goods for wealthier nations. Key studies of new global working classes have been located in Mexico, taking as their focus the interactions among class relations, work, gender, and household economies. Another key change, the emergence of large middle classes, has been less studied. Finally, Mexican migration to the United States is large and dynamic. This has provided a fertile field for Mexican and U.S. anthropologists, often working together. They have been leaders in developing the concept of transnationalism, that is, social–cultural practices that cut across conventional units such as “Mexico” and the “United States.” Migration is, in turn, closely connected to borders (e.g., Mexico’s borders with the United States and with Belize and Guatemala), and recent anthropology has begun to wrestle with the paradoxical combination of cultural crossing, economic inequalities, and political walls found in such places. In summary, Mexico is a place of nearly infinite complexity and cultural richness and is surely among the most stimulating and creative of all anthropological locations.

NATIONAL MUSEUM OF ANTHROPOLOGY

Although the National Museum of Anthropology in Mexico City's Chapultepec Park did not open its doors until September 1964, interest in the pre-Spanish heritage of the Mexican people dates back to the 19th century. This heritage includes many early civilizations, including the Aztecs and the Mayas.

Chapultepec Park has historically been a special place. The Aztecs were so impressed by the area's beauty that they made it the exclusive place of the emperors. The architecture of the building is similar to that of the Mayas, with its lower section built of smooth stone and the upper section decorated with geometric bas-reliefs. An imposing statue of Tlaloc, the Aztec god of rain, guards the entrance.

The museum contains 26 exhibit halls, each dedicated to a different culture. They are arranged around a central patio so that visitors may visit the halls in any order they wish. Good use is made of open air, and besides the main patio there are several other patios and a number of gardens. The fountain in the central patio represents the blending of the indigenous peoples with the Spanish to create a new culture.

The museum covers an area of 79,700 square meters. Besides the exhibit halls, it houses a library, areas for archeological and ethnographic research, restoration workshops, and storerooms. Far from being strictly a tourist attraction, the museum is viewed as an educational institution. It is a place where Mexicans can learn about their heritage and feel proud to be Mexicans. The exhibit halls are devoted to cultures such as the Toltecs, the Teotihuacans, the Mayas, and the Aztecs. People can trace their roots from pre-Hispanic Mexico to the Mexico of today.

Displays in the exhibit halls include dioramas and models that show the ways of life of the different cultures. Items on display include ceramics, sculptures, art, toys, and tapestries. Vividly colored Mayan frescoes greet visitors in the Mayan hall and afford a glimpse into the artistic tradition of the Mayan civilization. The Aztec room contains a diorama of the Tlalteloco market, a reproduction of

Montezuma's headdress, and the world-famous Aztec Calendar.

In an article about his memories of the construction of the museum, the architect Pedro Ramirez Vazquez wrote, "My greatest concern was to get the museum's message to all visitors and to increase their interest and get them excited about the relics and works of art."

MIAMI INDIANS

Miami (also called Maumee) is the name of an important Native American nation. Today, the Miami people live primarily in Ottawa County, Oklahoma, and in St. Joseph and Elkhart counties, Indiana. There are also Miami living in Peru, Wabash, Marion, Huntington, South Bend, Fort Wayne, and Indianapolis, Indiana. Tribal rolls in the Peru archives list approximately 6,000 persons of Miami descent. In the Oklahoma tribal rolls, the Miami number approximately 2,000.

French traders and explorers were the first Europeans to arrive in the Great Lakes region and in the Ohio Valley (1550–1600). Sent by the king of France, their primary goal was to chart the river systems as highways facilitating access into the interior of North America. Covered in dense impenetrable forest, the area was interconnected by canoe only. Even during the winter, when many river tributaries froze over, the smooth and unobstructed surfaces were more convenient for travel by dogsled. These French explorers, *habitants* (settlers), fur traders, and Jesuit missionaries discovered that the Miami were a traditional trading nation that controlled most of the Great Lakes region's waterways, possibly having forts at all of the major lake portages.

Linguistic anthropologists offer additional insights into the extent of Miami trading preeminence with the discovery that place names of geographical locations are not arbitrary meaningless designations applied for purely utilitarian purposes. Rather, place names carry symbolic import that also encodes historical data. Significantly, all of the Algonquin-speaking Native American nations of the Great Lakes region (e.g., Ojibwa, Ottawa, Menominee, Potawatomi) referred

to a great number of rivers as “the Maumee” and were unanimous in designating the Ohio Valley (criss-crossed by rivers bearing the Maumee appellation) “Valley of the Maumee.”

Little Turtle (1751–1812), the most famous Miami warrior chief, made an historic speech in 1795, when he delineated the relation of Miami to rivers during Treaty of Greenville negotiations. It is also remarkable that not one Native American nation attending the Treaty of Greenville negotiations registered a protest to Little Turtle’s sweeping claims.

As late as the 1800s, Tacumwah, the sister of Pacanne (chief of the Fort Kekionga Miami) and possibly a woman chief in her own right, exemplified the regulation of river trade by Miami in that she and her son, Jean Baptiste Richardville, “controlled the portage to the Wabash and enjoyed its revenues,” according to Stewart Rafert’s 1996 book, *The Miami Indians: A Persistent People 1654–1994*. Tacumwah “transported goods over the portage employing a number of Indians and their horses for that purpose and making a large profit” in the process.

The French documented Miami occupation of the current states of Illinois, Indiana, Michigan, Ohio, and Wisconsin. However, one must be cautious in using the English legal term *occupation*, with its attendant implication of property ownership, when speaking of Native American land use given that Native Americans did not recognize property ownership. This European (and especially British) concept developed most fully during the Industrial Revolution, when landowners succeeded in expropriating the peasantry’s “right of the commons” (ownerless land to be used by all) for the gathering of wood, herbs, and berries as well as for the grazing and watering of cattle and the like.

In contrast to land ownership, Native Americans insisted that all humans must share in nature’s largesse. Land was not understood as a commodity to be bought and sold. This Native American worldview became especially evident during early treaty negotiations with the United States as Miami, Ottawa, Menominee, Ojibwa, Potawatomi, Shawnees, Delaware, and other Native American nations described to U.S. government officials the Native American practice of mutual land use throughout the Great Lakes region and even beyond, not excluding people passing through. Major John Hamtramck’s negotiations with the Miami clans and other Native American nations offer a case in point.

Arthur St. Claire, governor of the Northwest Territory, sent Hamtramck to demand Native American acceptance of U.S. claims to the Great Lakes regions in 1790, during which time Hamtramck was continually frustrated by Native American refusals to meet with him separately and without the knowledge of other affected Indian nations. Hamtramck’s missives to the governor stated that Native Americans “could not give presently a proper answer before they consult the Miami nation, their eldest brethren.” The Kickapoo also refused to speak with Hamtramck until they had consulted the Wea Miami, and the Wea Miami would not negotiate with Hamtramck until they had received advice from the Atchachagouen Miami, “their eldest brethren.” The Atchachagouen warrior chief, Le Gris, told Hamtramck, “We cannot give a positive answer; we must send your speeches to all our neighbors and to the Lake nations.” The “Lake nations” also included the Shawnees and the Delaware. Apparently, this show of solidarity angered Hamtramck, who then, in partnership with General Josiah Harmer of the U.S. Army, attacked Miami villages and the autumn harvest, burning them to the ground.

What Hamtramck interpreted as an act of war may simply have been an egalitarian attitude shared by many Native Americans who advocate cooperation with others and nature rather than domination of them. Another of Hamtramck’s limitations may have been a lack of understanding of nomadic culture that has survival strategies and subsistence patterns very different from those of sedentary peoples such as Hamtramck. At times, even anthropologists and archaeologists have failed to grasp the difference between nomadic and sedentary cultures evidenced in the following comments: “Village fission and fusion is poorly understood; a village was abandoned, the entire village moved to a new locality, all of which conditions are then attributed to conflict or depletion of resources.” Although at times these conditions were true, it is not acknowledged that they are characteristic of specifically nomadic and seminomadic subsistence patterns.

Nevertheless, anthropologists Ermine Wheeler-Voegelin, Emily J. Blasingham, and Dorothy R. Libby made a major contribution to the study of Native American lifeways during the 1970s when they charted Miami seminomadic patterns at the behest of the U.S. Indian Claims Commission comparing Indian claims to use of land with historical documents. For

example, in 1688, the Miami of the Illinois River Valley abandoned this location, with some traveling to the St. Joseph River of southern Michigan, others to the Root River in eastern Wisconsin, and another group moving to the upper reaches of the Mississippi River. In 1695, Father François Pinet reported that the Wea Miami who lived near his mission (present-day Chicago) had formerly come from the Mississippi. During the autumn of 1698, Pinet remarked that none of the Miami villages was occupied due to the Miami subsistence pattern of following the winter game in the ubiquitous pattern of nomads and semi-nomads throughout the world.

The French missionaries and French traders described the Miami as living in large villages of dome-shaped wigwams near major waterways. During the spring, women planted corn, beans, squash, and tobacco, using hoes and digging sticks and staying close to their fields throughout the summer months. Both men and women fished, hunted small game, prepared animal skins, and gathered wild plants. After the autumn harvest, the Miami went into the wilderness to hunt deer, elk, black bear, and beaver while living in small temporary camps. During the spring, the dispersed population reorganized into bison-hunting parties that would travel the southern and western prairies, while others moved to maple forests for the collection of sap and also fished, taking advantage of the spring spawning season. Because French colonization of North America was relatively sparse, this subsistence pattern did not change substantially until the advent of Iroquois and British incursions into New France toward the middle of the 18th century. By this time, Miami had been allied with the French for at least 100 years by marriage, by gift giving between French government officials and Miami warrior chiefs (who were both men and women), and because the French by and large treated Native Americans equitably. Therefore, the Miami joined with the French to fight the British–Iroquois coalition. Unfortunately for the French and Miami–Ottawa-led Native American nations, the British were triumphant. Quebec surrendered to Britain in 1750, and Montreal surrendered in 1760. General Jeffrey Amherst sent Major Robert Rogers to take Fort Ponchartrain (present-day Detroit) in November 1760. On November 19, 1761, the British took possession of Fort St. Joseph on the St. Joseph River (River of the Maumee) in southern Michigan.

The Indians resented their treatment by the British. Whereas French gifts to the Native Americans had been generous, the British were parsimonious and far from cordial if Amherst's racist attitude toward them as "vermin" to be "exterminated" is any indication of British policy in general. This attitude also prevented the British from intermarrying with Miami, a fact that was not lost on Native Americans.

In 1763, the Ottawa chief Pontiac, in alliance with the Miami and other Native American nations, rose up against the British, who surrendered Fort St. Joseph in May and Fort Michilimackinac in June. By August, the British had lost every post east of the Allegheny Mountains except Niagara, Pitt, and Detroit, and although they held onto a few forts, they never again were able to impose British hegemony on the region. The American Revolution sealed the fate of the British, who ceded the Northwest Territory to the United States by the 1783 Treaty of Paris, but not until 1803 did the United States begin to actively take charge of the Great Lakes and Ohio Valley regions. Shortly thereafter, the Miami experienced accelerated culture change that had begun with the tragic loss of Native American lives due to a century of constant warfare and to European diseases such as smallpox.

In describing cultural transformation resulting from European contact, Charles C. Trowbridge had the advantage of being close to the American Revolutionary War and its consequent impact on Miami. Although his work *Meearmear Traditions* (published in 1823 and reprinted in 1938) was somewhat marred by contradictions regarding gender roles, he nevertheless recorded important ethnographic data. Given that he was not an anthropologist but rather a U.S. government agent, Trowbridge discounted what the Miami had to say about themselves, offering his own ethnocentric interpretations instead. On the one hand, he stated that there were "female chiefs, both of war and the village," and that "they are more implicitly obeyed than the male chiefs." Further on he stated, however, that women chiefs were "never listened to the first time." Trowbridge immediately contradicted this statement with "the influence of the woman [sic] chiefs is very great," also describing narratives that explicitly praised the exploits of warrior women. Perhaps Trowbridge may be forgiven for not having understood the social phenomena that he observed. However, this had the deleterious effect of obscuring Miami egalitarianism, although

Trowbridge's painstaking record of Miami customs strengthens an egalitarian hypothesis nonetheless.

The prerogative of women to actively pursue, choose, and desert their husbands and lovers is one indication that a society is egalitarian. Miami women simply walked away from undesirable liaisons, as did men. Both sexes fished and hunted, suggesting that there was little division of labor. For instance, the woman trader Tacumwah organized her own separate hunts.

Miami attitudes about raising children also suggest egalitarianism. Trowbridge recorded that boys and girls were treated with the same affection and that legitimate children were not differentiated from illegitimate children. It was common for unmarried Miami women to have children, and their "reputations" were not affected by doing so. Permitting women to defend themselves is also an indication of high status for women and egalitarianism. If a Miami man physically attacked a Miami woman, she had the right to kill him. Murder, if committed by a woman, was subject to the same punishment as if committed by a man. In nonegalitarian societies, it is usual for women to suffer harsher treatment than men for the same offense. Originally, Miami descent may have been determined matrilineally given that a male Miami chief's "successor" was not his own son but rather the son of his sister. Matrilineality and the importance of the sister's son is often a concomitant of egalitarianism.

The ethnohistorian Rafert offered insights into Miami culture change by documenting the hegemonic forces that influenced Miami to join the Euro-American market economy. Assimilation required the suppression of the Miami and French languages, both Catholicism and Miami Shamanism, as well as egalitarianism. The Miami leader, Meshingomesia, became wealthy during the 1830s after becoming a Baptist minister. He encouraged male agriculture in violation of Miami custom, for traditionally farming was the occupation of Miami women, who then owned the product of their labor. Meshingomesia also pressured Miami elders to permit Miami tribal lands (held in common) to be sold to private owners. Religious pressures for Miami to assimilate were apparently so acute that in 1846 the non-Protestant Miami were marched under armed guard to Kansas Territory, with many of them dying along the way due to exhaustion, hunger, and/or exposure. The Baptist Miami who lived on Meshingomesia's land were not

subject to this removal action. In 1873, the Miami people on Meshingomesia's land were also granted exemption from taxes and mortgages.

Whereas Rafert interpreted economic incentives that encouraged Miami to convert to Baptist Christianity as a phenomenon "strengthening tribal leadership," there is an alternative explanation for this Protestant conversion story. Although conversion of Miami by male Baptist ministers strengthened male tribal leadership, it may have done so by usurping women's political power. By the 1850s, all of the most important male Indiana Miami leaders had converted to the Baptist religion, and at the same time Miami councils were becoming all male, thereby disenfranchising Miami women. Yet Miami matrifocal tradition must have remained viable despite patrifocal trends. Ozahshiqua (ca. 1810–1877) seemed to have retained her independence, being the sole owner of many horses and 850 acres of land (the Ozahshiqua Reserve) until her death.

The Indiana Miami are the descendants of Miami who escaped the 1846 removal by the U.S. government. Following widespread starvation and impoverishment after removal to the largely unknown ecosystem of Kansas Territory, some Miami migrated to Missouri in 1860 and many Miami made their way back to the ancestral heartland of Indiana. Eastern Miami who were not forced to relocate to the western territory, and who were joined by returnees from forced removal, were ultimately divested of all treaty rights in 1897.

The U.S. government still has not "recognized" the Indiana Miami at the time of this writing, meaning that they are disqualified from receiving compensation for the expropriation of their lands, the near extinction of their language, and the loss of their ancient religious traditions. Nor do Indiana Miami receive government health care or other services and resources received by "recognized tribes" to which the Oklahoma Miami belong. The Indiana Miami have been fighting nonrecognition ever since Robert Owens, a descendant of the famous Chief Richardville (Richerville) and Chief La Fontaine, began proceedings to regain federal recognition during the late 1970s. By 2005, they still had not gained recognition, even though genealogical data linking the Oklahoma and Indiana Miami are indisputable.

MIDDENS

Middens are prehistoric rubbish or garbage heaps. The word *midden* in archaeology is a term that is truly a product of this discipline and is now part of its everyday vernacular. Middens are one of the most useful deposits for archaeologists because nearly everything a group of people use in their daily lives eventually will be lost or discarded, and most of what is thrown away ends up in a midden. These archaeological deposits can contain everything from broken tools to used-up artifacts, shells, plant materials, bones, charcoal and ash from fires, and even human remains. Midden contents indicate where people went to obtain their food, what proportions of different foods comprised their diets, and how the types of food and other items may have changed over different seasons or over long periods of time. The deposition of grease and other decomposing organic materials from human habitation means that midden soils typically are darker in color and contain more nitrogen than the natural surrounding soils. Because they are most commonly associated with the accumulation of mollusk shells from food consumption, middens often are referred to as shell middens, shell heaps, or shell piles.

The word *midden* is derived from a Scandinavian word that means kitchen leavings and was traditionally

called “kitchen midden,” which is a literal translation of the Danish word *køkkenmøddinger*. Japetus Steenstrup, a Danish zoologist, first noted that these deposits were not natural but in fact were the result of human waste accumulation and thus would be of archaeological interest. In 1848, the Royal Academy of Copenhagen established a committee to study these kitchen midden sites, and the committee members were the archaeologist Jens Jacob Asmussen Worsaae, the geologist Johan Georg Forchhammer, and Steenstrup. Their findings demonstrated that these midden deposits could assist not only in the interpretation of past environmental conditions but also in the understanding of prehistoric artifacts. They also helped to prove the viability of the “three-age system,” that is, the development over time of stone tools to bronze tools and then to iron tools. Investigations of mollusk shell piles associated with Danish Mesolithic sites, and the heated debate surrounding the origin of these deposits, led Steenstrup to seek similar materials from kitchen midden sites in Greenland during the 1870s. Unlike the Danish sites, these refuse piles were composed primarily of seal and caribou bones. However, the artifacts associated with these tossed food remains documented several cultural layers of deposition and the presence of an early Arctic culture, which made tiny stone tools, that was distinctly different from more recent Inuit deposits.

Coincident with Steenstrup's Greenlandic research, the American geologist William Healey Dall began systematic excavation of stratified “shell heaps” on the Aleutian Islands and interpreted these as three distinct evolutionary stages of subsistence based on their faunal composition and recovered artifacts. Across the Pacific, excavations were under way on the Omori shell midden near Tokyo Bay, where the American archaeologist Edward Morse identified distinct cord-marked pottery that is now recognized to be some of the oldest pottery in the world and attributed to the Jomon culture. In 1902, the German archaeologist Max Uhle excavated a large shell midden at Emeryville on the east shore of San Francisco Bay. Uhle was able to determine two major components characterized in part by the dramatic shift from oysters to clams. Since that time, shell middens have been investigated on nearly every coast from the Shetland Islands to South Africa and from New Zealand to Florida.

MIDWIFERY

Attendance at birth has been suggested to be essential in facilitating mother–child survival as the physiology of birth changed during human evolutionary history. *Midwife*, an Anglo-Saxon term meaning “with woman,” aptly describes the role that women have long assumed as birth attendants. The anthropology of midwifery is the study of nonphysician primary birth attendants within and across cultures. Birth attendants are not always specialists, and not all cultures have specifically delineated roles for birth attendants. Thus, our definition of the anthropology of midwifery is expansive enough to include a wide range of biomedical and nonbiomedical, as well as formal and informal, birth attendants. Important elements of study in this field include the definition, education, practices, identities, and knowledge systems of midwives. Much anthropological research is directed toward the documentation and critique of ongoing international battles over the definition and social roles of midwives, especially as viable alternatives to the overmedicalization of birth.

There is a sharp distinction made in international literature and discourse between “professional midwives” and “traditional birth attendants” (TBAs). Health authorities tend to accept this distinction, whereas anthropologists tend to reject or contest it, examining the social roles of definitions as tools of power to determine insiders and outsiders. The international definition of a midwife was created by the International Confederation of Midwives and formally accepted by other international organizations,

including the World Health Organization (WHO) and the International Federation of Gynecologists and Obstetricians:

A midwife is a person who, having been regularly admitted to a midwifery educational programme duly recognised in the country in which it is located, has successfully completed the prescribed course of studies in midwifery and has acquired the requisite qualifications to be registered and/or legally licensed to practise midwifery.

She must be able to give the necessary supervision, care, and advice to women during pregnancy, labour, and the postpartum period, to conduct deliveries on her own responsibility, and to care for the newborn and the infant. This care includes preventative measures, the detection of abnormal conditions in mother and child, the procurement of medical assistance, and the execution of emergency measures in the absence of medical help. She has an important task in health counselling and education, not only for the women but also within the family and the community. The work should involve antenatal education and preparation for parenthood and extends to certain areas of gynaecology, family planning, and child care. She may practise in hospitals, clinics, health units, domiciliary conditions, or in any other service.

Those who meet this definition may be fully incorporated into health care systems; those who do not (the TBAs) may suffer multiple forms of discrimination. Since 1992, the WHO has defined the TBA as “a person who assists the mother during childbirth and initially acquired her skills by delivering babies herself or through apprenticeship to other traditional birth attendants,” distinguishing trained TBAs as having “received a short course of training through the modern health care sector to upgrade her skills.” The WHO suggests that TBAs are stopgap measures until more “qualified” personnel are available.

Midwifery in the Developing World

Nongovernmental organizations, multilaterals, and bilaterals have invested heavily in professional midwife and TBA training for more than 40 years in their efforts to reduce maternal and perinatal mortality in the Third World. The anthropology of midwifery grew out of this trend and reflects anthropologists’

roles in analyzing TBA training programs for development organizations and the impact of new models on both quality of care and health outcomes. Women trained as official midwives are usually young and have borne no children themselves. They usually are educated in an urban environment and then sent out to serve in rural villages, where they wear the white coat and expect respect from the townspeople for their professional educated status. They usually work in underfunded and understaffed government-built clinics, but for an extra sum of money they will sometimes attend home births if they are called. Workloads and stress levels in such clinics are high, often resulting in maltreatment of women and early “burnout” on the part of midwives.

While some governments have established programs designed to encourage birth in clinics and hospitals, many rural women resist and prefer, instead, to give birth at home with the help of midwives (TBAs). Community midwives are usually older mothers who have become midwives when they were asked to attend the births of friends and relatives. Some embark on long apprenticeships, while others learn gradually and less formally by simply attending births. From the local point of view, the biggest difference between community midwives and professional midwives is that community midwives are recognized by their community as legitimate birth attendants, whereas professional midwives are often seen as young and inexperienced women who must prove their worth to the villagers before they can be trusted.

TBA training courses have been highly criticized for their pedagogy and ideology. The purpose of these courses has generally been to educate TBAs in how to identify risks that require transport and to improve their prenatal and maternity care. Designed by biomedical personnel, course content is often inappropriate given local circumstances and realities. Courses often assume access to material resources that are lacking locally, are taught in a style that is inappropriate given the literacy skills and learning styles of midwives, and fail to provide TBAs with a respected and effective place within an integrated system of medicine. Many anthropologists have called for the replacement of such top-down systems with models of mutual accommodation. But the worldwide hegemony of Western biomedicine has made this an elusive goal. When professional midwives make a sincere effort to learn about and honor local customs and

traditions, when they approach local people with an attitude of respect, and when they demonstrate a willingness to work with community midwives, mutual accommodation is achievable.

It is important not to romanticize or demonize professional or community midwives. Both work under discriminatory biomedical systems, and both usually try to give skilled and considerate care and remain, in many parts of the world, the only viable option for millions of women. Anthropologists question the wisdom of dividing professional midwives and TBAs in a hierarchical way that allows government agencies and development planners to support one group while trying to exterminate the other and to suggest that a “real midwife” may be recognized as such by either her government or her community.

Midwifery in the Developed World

Changes in midwifery in the developing world are intimately linked to debates over midwifery in the developed world, where professional midwives provide care for the majority of pregnant women. Their education is generally university based and often postgraduate, giving them skills in research and publication unavailable to midwives in the developing world. They practice in hospitals that are usually well staffed, well funded, and replete with medical technologies. Their major dilemmas are ideological; they struggle both in thought and in practice with the tension between what they themselves call the “medical” and “midwifery” models of care.

Obstetrical dominance over birthing represents not a neutral substitution of one care provider by another but rather a fundamentally different and opposing philosophical approach to birthing care. In the United States and Canada, obstetric control over birth was cemented during the early 1900s, and midwives were nearly eliminated. Since then, midwives have been attempting to achieve their renaissance. American midwifery is split between nurse-midwives (trained first in nursing and then in midwifery), who practice mostly in hospitals and attend approximately 8% of American births, and direct-entry midwives (not additionally trained in nursing), who practice mostly out-of-hospital and attend approximately 1% of births. In Canada, midwifery was illegal until 1993, when it was legalized in Ontario through the work of a coalition of nurse- and direct-entry midwives, a process that has since continued in other Canadian

provinces. The reclaiming and revitalization of midwifery in both countries has resulted from alliances among activist consumers, midwives, and others. European, Australian, New Zealand, and Japanese midwives are engaged in a process of self-examination, attempting to reclaim the autonomy they lost with the obstetrical takeover of birth during the 19th and 20th centuries.

Hundreds of professional midwives in the developed world regard traditional midwives in the developing world as their ideological “sisters” and are working to support and sustain the preservation of traditional midwifery and its future development. Such midwives combine elements of traditional and professional midwifery knowledge in their personal practices, dedicating their professional lives to being, and helping others to be, “with woman” during the processes of pregnancy, birth, and the postpartum period.

Although it is debated whether *Homo sapiens sapiens* emerged in Africa alone or via a trellis work of interacting places across the Old World, migration certainly accounts for the remarkable spread of humanity across the world. To take three dramatic examples, pioneers on simple boats reached Australia no later than 40,000 years ago, the New World was populated (probably on foot across land bridges) no later than 13,000 years ago, and remote Pacific islands have been settled over the past 3,600 years by sophisticated navigators using outrigger canoes. Nor were these pioneering movements into unsettled areas the only instances of migration in the human past. Many waves of migration and cultural change (it is hard to separate these) have shaped the map of world culture regions. A characteristic example is the Bantu expansion, associated with tropical root crops, iron working, and cattle, spreading south and east across sub-Saharan Africa.

Mobility in small-scale societies takes place through group fissioning after disputes (often when existing groups grow in size and have become crowded) and through cross-spatial marriage and gift exchange networks. Such movements can become migrations (a directional flow) for varied reasons, including environmental changes and innovations in social organization and food production. We see the results of such flows as a “diffusion wave” across a large spatial scale. In the past, simplistic and often speculative models envisioned migrations as vast and dramatic movements of conquerors or adventurers. Today, we piece together more complex and gradual changes from three sources of evidence: genetic branching, historically related languages, and the archaeological record. It is often unclear whether a diffusion wave represented the migration of new people, the conversion to new cultural practices and social organizations, or both.

As societies became larger in scale, politically centralized, and more unequal, new patterns of migration emerged. Violent political expansion and consolidation—warfare and repression of subject peoples, especially religious and political dissenters—became a cause of migrations, continuing to the present day. Centralized states deliberately relocated populations and encouraged colonizers, often to consolidate frontiers and sometimes to encourage the production of desired crops. Meanwhile, wealthy centralized cores presented targets for militarily skilled raiding populations, who both displaced other

Migrations are a constant in human history. Indeed, it is a mistake to treat residential stability as normal and thus not needing explanation while treating migration as abnormal, novel, and thus uniquely needing explanation. Unfortunately, this has not been the way in which the social sciences (including anthropology) have developed, and this entry focuses on migration with only brief mentions of the distinctive, and sometimes unusual, conditions favoring stationary or repetitively circulatory cultures.

peoples and themselves settled down and changed culturally. As a result of these various processes, diasporas formed important commercial, artisanal, and religious networks.

An important phenomenon, labor migration by peasants, links the world of premodern complex societies with the modern migratory world. Situations in which landlords freeze peasants into place through rigid labor duties are important but have never been universal and have broken down thoroughly as capitalism has expanded. Peasants often have too many children to inherit access to land, and those extra sons and daughters then migrate. In some cases, they open up new land, but this option is limited, so that they often become labor migrants in cities and expanding commercial agricultural frontiers. The capitalist world system stimulates migration through the modernization of agriculture in sending areas, the displacement of peasants from previously intensive labor systems, the impact on hand artisans by industry, and the collapse of putting-out production systems. On the other end, employers actively recruit new workers to undercut existing workers or during periods of expanding production. Hence, it is dynamic social change, rather than stagnation and poverty, that causes people to leave their accustomed homes.

The capitalist world system has seen four major kinds of migration: commodity slavery (especially the African slave trade to plantation regions of the New World), displaced peasants from Asia and Europe to the Americas and within these regions, migrations of specialized businesspeople and skilled workers, and refugees from persecution. Even the latter become labor migrants as they find ways of surviving in new economies. Migration includes both internal movement and international movement, which tend to be conceptualized and studied as if they are different but in fact have similar social dynamics except in terms of political status as a national or nonnational matter. For example, internal migration studies often focus on the topic of urbanization of rural people, but this is an important feature of international migration as well.

The nation-state does matter, in particular the status of "citizen." Citizenship, which began in city-states, constitutes an equal collective access to various rights and institutions in exchange for loyalty to the central national executive (e.g., paying taxes, doing military service). But as citizenship collects together insiders, it also excludes outsiders, such as migrants, or creates ambivalent transitional categories for them. Hence, for anthropologists to understand the migrant experience, it is also necessary to understand the specific cultural construction of the insider/outsider divide.

Cultural anthropologists, with their predilection for studying the powerless and culturally distinctive, have provided a large number of ethnographies of migrants, many of which are of excellent quality. They have shown that migration does not necessarily lead to social disorganization and have emphasized the importance of networks for migrants. Anthropologists have explored the concept of transnationalism, in which mobile communities of people have social, cultural, and political presence in more than one nation at a given time. They also have looked at the nuances of social, cultural, and political incorporation into new societies. And recently, critical anthropologists have turned their fine-grained ethnographic focus to the articulations between migrants and dominant populations, including the division of labor and business markets into migrant and nonmigrant segments, the mechanisms of exploitation of the surplus produced through that segmentation, and the borders and other devices of legal classification and enforcement that migrants encounter in their journeys across nation-states.

MIGRATIONS TO THE WESTERN HEMISPHERE

The peopling of the Western Hemisphere is currently a matter of great controversy. Until recently, the traditional view was that some 12,000 years ago, people came from Asia to the Americas. This theory claimed that during the last Ice Age, the sea levels of the world were several hundred feet lower than they are today because enormous

quantities of water were locked in the glaciers covering much of the Northern Hemisphere. Lower sea levels created a land bridge between Siberia and Alaska at the point where the Bering Straits are today. The Bering Land Bridge allowed early hunter-gatherers to cross over from Asia to North America as they followed the migrating herds.

In the traditional view, the peopling of the Americas was a movement from north to south. Until recently, the oldest settlements and other archaeological evidence of humans had been found at Clovis, New Mexico. Scientists speculated that other sites that would have been along the migration route on the Pacific coast would have been covered with water long ago. During recent decades, a variety of evidence that challenges the traditional Siberian migration theory has been discovered.

Debates over the issue of the peopling of the Americas have questioned the number of migrations, the places of origin, and the times of the migrations. Evidence that is challenging the traditional view is archaeological, anatomical, linguistic, and genetic. Archaeological evidence that the peopling of the Americas happened in a different way includes the discovery of settlements in South America dated at 40,000 years old. Other sites, older than Clovis, have also been found in North America.

Evidence also suggests that early humans may have traveled in boats across both the Pacific and the Atlantic to reach the Western Hemisphere. Thor Heyerdahl sailed the Atlantic and Pacific in primitive boats, proving that it was possible that early people could have reached the Western Hemisphere from Polynesia and Africa. The coastal entry theory of migration argues that prehistoric people arrived in the Western Hemisphere by boat from Europe or from areas in the North Pacific or South Pacific.

Based on linguistic evidence, some researchers have argued that there were three major migrations across the Bering Land Bridge. The linguistic evidence has recently been supported by genetic evidence suggesting that genetic markers and anatomical features in Native Americans and in Asian groups have strong resemblances.

MINTZ, SIDNEY WILFRED (1922–)

Sidney Wilfred Mintz is a major figure in anthropology's synthesis of the study of local people and places with world history, and he has contributed significantly to the anthropology of food, work, the Caribbean, and the African American experience. He received his Ph.D. in anthropology from Columbia University in 1961. He spent most of his career at Yale University and the Johns Hopkins University, where he was William L. Straus, Jr., Professor of Anthropology. He was a stimulating and much beloved teacher. Mintz, together with Eric Wolf, William Roseberry, Eleanor Leacock, June Nash, and others, developed the neo-Marxist school in anthropology that is often called "political economy."

Mintz was a member of an influential cohort of students of Julian Steward, who significantly advanced the cultural anthropological study of complex societies, and worked on Steward's *People of Puerto Rico* project. Mintz studied an industrial sugar plantation region of the island's south coast and, together with his close friend and fellow Steward student Eric Wolf, authored a key article comparing haciendas and plantations. This work pioneered the idea that the various social and cultural formations of Latin America and the Caribbean were shaped by their connection to world capitalism over long historical periods rather than being traditional societies only recently affected from the outside; the work anticipated and influenced "dependency" and "world systems" theorists of the global economy. Mintz also compiled a much admired life history of a Puerto Rican sugar cane plantation worker who was also his close friend, Anastacio (Taso) Zayas (*Worker in the Cane*), contributing significantly to the anthropology of work, the study of political and religious change, and life history studies.

Mintz continued in Caribbean ethnography, working in Haiti and Jamaica among former slave populations-turned-free peasants and offering a variety of influential articles on market systems as forms of articulation, Creole languages, and so forth. This culminated in an innovative approach to African American cultural history in a coauthored book with Richard Price. Previous work either had seen slaves as being wiped clean of culture due to the oppression of the experience or had searched for specific African culture traits surviving in the Americas. Mintz and

Price argued instead for specific cultural processes within the slave communities themselves, notably the development of shared African American Creole cultures. Mintz continues to explore the Caribbean experience, recently arguing that this region anticipated globalization in the sense of developing new and open-ended cultures as part of global connections from Columbus onward while at the same time maintaining an experience and ethos of local place.

In *Sweetness and Power* (1985), Mintz followed sugar from the production sites in the periphery (industrially organized plantations even during the slave era) to consumption sites, linking sugar as a "drug" to the changes in factory and household work caused by the core's industrial revolution. Thus, he widened our understanding of capitalism, bringing into consideration pleasure and consumption as well as toil and also bringing into consideration geographic sites such as the Caribbean as much as Great Britain and other archetypically modern locales. Mintz continued to develop the anthropology of food in *Tasting Food, Tasting Freedom* (1996), which explored the consumption of food as an arena in which people assemble cultures out of wide-ranging components and relationships in the world economy. Finally, he has articulately restated the case for in-depth ethnography, even as he is noted for his exploration of long historical and global-scale processes.

MISSING LINK

The phrase *missing link* is a colloquial term describing a transitional form between taxa in an evolutionary

scheme. Because the primary tenet of evolution is morphological change over time, there is necessarily going to be transitional forms between any two species sharing an ancestor–descendant relationship. Charles Darwin recognized this, and in fact the apparent lack of transitional forms was one of the most significant concerns he expressed in *The Origin of the Species*. This concern reflected Darwin's belief that evolution occurred primarily through gradual changes. Therefore, most species at any one time in the past would be in a transitional state, and the fossil record should be full of such examples.

During the decade following the publication of *The Origin of the Species*, this philosophical idea came to underlie many subsequent works on evolution. A strong form of this belief was the development of recapitulation laws by several different researchers, most notably Ernst Haeckel. The law of recapitulation states that evolutionary adaptations proceeded as additions to the development cycle of organisms (ontogeny) and that, therefore, organisms encapsulate the adult morphology of their ancestors during their own growth and development. In other words, ontogeny recapitulates phylogeny. The development of genetics and embryology eventually discredited the simple idea that additional developmental stages are the sole mechanism of evolution, but the idea had a great impact on later research.

During the 1940s, Richard Goldschmidt proposed the idea that evolutionary novelties might have appeared instantaneously, within one generation, through mutations in parts of the genome responsible for developmental changes. This idea became known as the “hopeful monster” hypothesis. Although there are a few limited cases of significant change that can occur between generations (e.g., possibly hairlessness in the naked mole rat), the vast majority of mutations affecting major developmental sequences are lethal or extremely maladaptive. The upshot of the hopeful monster hypothesis is that evolutionary change could occur nearly instantaneously and that transitional forms might not exist at all in some cases. This hypothesis is largely considered incorrect with regard to phyletic change, but modified forms of the hypothesis that focus on fast evolutionary change are still strongly considered for particular evolutionary sequences. Punctuated equilibrium, in particular, was strongly influenced by this idea.

When the term *missing link* is used, many individuals think of transitional forms between very disparate

taxa such as *Archaeopteryx*, which has been presented as a transitional form between birds and reptiles. However, taxa do not reproduce to create other taxa. Rather, individuals reproduce to create other individuals. Therefore, the only true missing links that can exist are individual organisms that form a distinct lineage. There is no single individual that marks a transition between ancestor and descendant; instead, all conspecifics are links with characteristics that show variation. The limits of the fossil record might seem to show *Archaeopteryx* as a fantastic chimera of avian and reptilian features, but the individual specimen was simply a member of a variable lineage and was little different from its parents or its offspring. There are rarely hopeful monsters in evolution.

The politico-religious creationism movement has focused much of its antievolution effort on the erroneous concept of missing links. Creationists often challenge researchers to provide morphological intermediates clearly linking widely disparate taxa. However, when presented with such fossils, they claim that the fossils simply show a different species or member of one of the proposed ancestor/descendant species. These groups never accept any evidence as truly transitional. Fundamentally, there is an expectation that researchers provide the ultimate missing links—individuals—and then sequence every individual that existed between two disparate taxa, else there still be missing links in the ancestral chain between them. The paleontological record will simply never accommodate such an expectation due to taphonomic and collection bias.

There will always be gaps in the paleontological record and, therefore, missing links in the evolutionary sequence of virtually all species. Evolutionary change happens over time (whether relatively quickly or slowly), and a simple typological approach that expects the fossil record to show perfect morphological intermediates connecting taxa is unrealistic. Missing links are not a failing of evolutionary explanation; rather, they are simply a consequence of the limitations of the fossil record.

MODAL PERSONALITY

Modal personality was the term used by anthropologist Cora DuBois in her 1944 monograph *The Peoples of Alor: A Social-Psychological Study of an East Indian Island*, based on research carried out in the Alor islands of Indonesia during the late 1930s. The Alor study focused on issues and methods involving both anthropology and psychology. It was designed specifically to explore cross-culturally the potential for the existence of a basic human personality structure embedded in specific sociocultural settings and social-institutional structures. The academic quest was for an applicable statistical mode of analysis to be used in studying personality trait variance cross-culturally.

Methodologically, DuBois applied, tested, interpreted, and integrated standard culture and personality methods supplemented by then standard psychoanalytic testing methods. Many of the research concerns focused on in DuBois's fieldwork, regarding the structure of human personality, were addressed at seminars of the New York Psychoanalytic Society. This forum was headed by Freudian psychoanalyst Abram Kardiner, who had received training in Boasian anthropology. The challenge was to formulate psychocultural testing procedures and explanations in the search for the existence of basic personality differences and similarities while simultaneously exploring the potential for specific personality types linked to specific cultural institutional structures in varying cultures.

What developed from DuBois's fieldwork was the concept of a modal personality. *Modal personality* was defined in *The People of Alor* as "the product of the interplay of fundamental physiologically and

neurologically determined tendencies and experiences common to all human beings acted upon by the cultural milieu, which denies, directs, and gratifies these needs very differently in different societies." In other words, biology provides the physical backdrop for an innate personality structure that is then molded by specific cultural practices/institutions in the development of unique group personality types. Cultures then adapt to their surroundings through selected reinforced attitudes, actions, beliefs, and values based on the available basic human biological mental structure. Personality in and of itself was recognized as a biological given. Specific personality formulations were then conceived of as a product of the social structure of the community. DuBois assumed from the beginning that there existed a "psychic unity of mankind" or a template on which a society further designs, redesigns, and manipulates personality traits according to that culture's unique and varied needs. Specifically, DuBois studied the relationship of variations in early mother-infant interaction, care, and treatment and the effects on later personality development within the Atimelang people on the island of Alor.

The primary methodological assessment tools used by DuBois, as shown by William Manson in *The Psychodynamics of Culture*, included autobiographies, life cycle descriptions, personality development, and projective tests (e.g., Rorschach test interpretations, children's drawings, responses to the Porteus maze, word association responses). All were standard tests used in psychoanalytic studies at the time.

DuBois's research was backed financially and professionally by the Science Research Council of Columbia University (Ruth Benedict) and was supported by noted culture and personality anthropologists of the time (including Margaret Mead and Gregory Bateson). The ongoing discussion seminars at the New York Psychoanalytic Society, run by Kardiner and others, formed the backdrop for presentations and interpretations of the ongoing research of DuBois and others. At the same time, Kardiner was developing his own theory of a basic human personality structure, later published in several different articles and texts. Kardiner's research into basic personality structure was described as an important milestone for both psychoanalytical and anthropological studies. This research was supported by other researchers such as Melton Singer, who commented that Kardiner's work was important because

it “combined both psychoanalysts and anthropologists into a new synthesis,” interpreted as providing the possibility of a crossing and/or blending of traditional disciplinary boundaries.

The methodological device, applied by DuBois to the Alor population, included the application of both quantitative projective and nonprojective testing procedures in a fieldwork situation. At the time, anthropology was primarily qualitatively driven by methodology, so this was a new and exciting opportunity to bridge the gap between quantitative and qualitative research tools. The content of various tests, as applied in extensive fieldwork situations, was analyzed—not just by the primary researcher (DuBois), the anthropological standard of the time, but also including various quantitative and qualitative tests and data analyzed independently by nonanthropological behavioral scientists not present at the fieldwork site. This was in part an attempt to control experimental bias, as defined in the psychoanalytic field. DuBois supplied the ethnographic data to other researchers, not present in the field, who then interpreted, analyzed, and compared their findings with those of DuBois. The psychotherapist Emil Oberholzer was one of the independent interpreters of the Alor Rorschach test materials results, as was Kardiner, who independently analyzed the data collected on completed autobiographies of the Alor. It was one of the first times that this type of statistical analysis was being applied to ethnographic fieldwork in the culture and personality subfield of anthropology.

In the 1966 update of *The People of Alor*, DuBois refined her original modal personality concept by clarifying and delimiting her original concept: “Modal personality was the term I proposed at the time to designate central tendencies in the personalities of a group of people studied by means of more or less objective and cross-culturally applicable tests, as well as by means of observation and autobiographies. Modal personality was not an explicative concept. It was a purely static and descriptive one.” In other words, what she chose to use was a part of many techniques that were available for field-workers at the time, not the sole criteria for establishing personality structure.

Early reactions to the concept of a modal personality varied but did trigger additional research on the subject by other anthropologists in different fieldwork settings. Anthony Wallace applied the modal personality and Rorschach protocols, developed by DuBois, to the Tuscarora Iroquois Indians of New York in his

work titled *The Modal Personality of the Tuscarora Indians*. His primary research focused on exploring the existence and causes for deviant personality types. Wallace examined community influences on the molding of basic personality types. He engaged in a methodological refinement of DuBois’s modal personality methodology that both supported and enhanced DuBois’s initial use of systematic, objective testing assessment tools in searching for a basic personality type. Where Wallace experienced difficulty was in his ambitious attempt to collapse several different concepts including a modal personality: national personality, basic personality, social character, ethos, temper, psychological culture pattern, genius, and communal aspects of personality. He believed that they all referred to a “common class of phenomena,” and this flaws his otherwise valuable work on the Tuscarora Iroquois and his methodological contributions. Yet we should also look at the work of Victor Barnouw, who in *Culture and Personality* further contributed that *modal personality* has been used interchangeably with *basic personality structure* by several researchers. Obviously, there have been issues surrounding this concept as a valid and distinct category in anthropology.

George Devereux next took the concept of modal personality and suggested that it be divided into two separate and distinct models—one psychological and the other sociocultural—each with its own form, content, and structure. Devereux’s contribution was that social scientists and psychologists approach the same subject matter from very different theoretical and methodological stances. They are asking different questions and using different conceptual frameworks, so it is obvious that they also need to use different models of this same concept. Devereux suggested that there were basic differences between the “psychological–psychiatric (subjective) and sociocultural–historical–economic–political (collective) explanations of human phenomena. These two sets of disciplines study radically different phenomena.” There was anxiety being created that anthropology was possibly being collapsed into psychology even though it is, was, and should remain a separate and distinct field. Devereux further supported his suggestion of a dual modal division by pointing out that psychiatry–psychology tends to focus on the individual (psychological), whereas the discipline of anthropology tends to focus on the group (collective) or the social phenomena. He included a Hungarian

example to further illustrate his point of a difference between motivations of the individual Hungarian person and the motivations of the Hungarian people as a social group relative to a particular political topic. The individual and the group do not interpret reality in the same way because their motivations are different. Devereux attempted to show that because the motives would not be the same, the two factions should and must be studied and interpreted differently. Devereux was clearly stating that *modal* operates on at least two different levels and must be researched and analyzed with this in mind.

MODELS, ANTHROPOLOGICAL

Models are simplified representations of reality that help people to handle the largely undifferentiated mass of stimuli that impinges on their senses. *Model*, then, is a generic term for any systematic set of guesses or interpretations that people make about their surroundings. Some writers label these models as theories, hypotheses, theses, paradigms, propositions, or even just ideas. This entry discusses only two broadly applicable models: folk and analytic.

The models that guide us through our everyday concerns may be termed *folk models*. We have little control over these models; they were here before we were born, and we learned them as impressionable

children. In practice, folk models tend to reflect the interests of the socioeconomic elite. Such an outcome might be expected given that members of the elite have the inherent power to control communications and symbols, to reward respectful behavior toward themselves, and to bring sanctions against those whose behavior expresses a dangerous deviation from “model” behavior. Folk models are stereotypical, specific, complex, largely supraindividual, and normative; use as little information as possible for as broad a formulation as possible; and contain no inherent mechanisms through which they may be tested, doubted, questioned, or rejected.

Analytic models, in contrast, are processual, general, simple, individually created, and explanatory and use as much information as possible to form as succinct a hypothesis as possible. Investigators create analytic models to explain what they observed. Folk models do not actually explain behavior and beliefs; instead, they label, justify, and valorize behavior and beliefs.

The components of both analytic and folk models are structure, function, and process. Structure refers primarily to description, which in analytic models is usually phrased in culturally neutral terms from an observers’ viewpoint. Description in folk models, however, is only from the actors’ viewpoint.

The function of a cultural entity refers to the consequences of its performance. These consequences, however, might not necessarily be the same as the conscious intention of the people. In fact, the long-term effect of the practice of many cultural beliefs and behaviors may be unintended and nonarticulated so far as the day-to-day life of the people is concerned. These hidden consequences are known as latent functions and are part of an analytic model; folk models do not contain a latent function.

Process is the component of models that handles change, history, and evolution. Process in most folk models is quite distorted, generally serving to indoctrinate members of a society with culture-specific values. Process in most analytic models reflects an empirical grounding in documented facts.

Analytic models are not superior to folk models; they simply serve different purposes. It might be expected that the use of analytic models will sharpen our powers of observation, stimulate our thinking, cause us to question the values and judgments that we once accepted without question, and encourage self-understanding. Finally, analytic models should help us to develop a degree of detachment in confronting

the issues of life; we should realize the flexibility of our own beliefs and standards as well as those of society.

MODJOKERTO

In 1936, Ralph von Koenigswald announced the discovery of a fossil cranium from a very young child outside the village of Peking, near the city of Surabaya, in East Java. Unlike most of the fossil hominids from Java, the cranium of Modjokerto reportedly was recovered in situ. Recent dating of the specimen, using the new $^{40}\text{Ar}/^{39}\text{Ar}$ dating method, places Modjokerto at 1.81 million years ago. This is puzzling given that the earliest *Homo erectus* from Africa are placed roughly at the same date.

Assuming that early hominid skulls matured at the same rate as modern humans, the cranium of Modjokerto is that of a 4- to 6-year-old. It is nearly complete but is missing most of the face and parts of the base. It has a very small cranial capacity of approximately 650 cubic centimeters. If the child had survived into adulthood, the brain case would have grown to approximately 700 to 750 cubic centimeters. Based on the immature physical characteristics, von Koenigswald initially considered this specimen to be a new species that he named *Homo modjokertensis*, whereas Cora DuBois regarded it as a youthful representative of Ngandong Man.

Given its young age, the anatomical characteristics that would positively identify the species of the Modjokerto child had not yet developed. However, some beginnings of a *H. erectus* cranium can be seen,

including a small but projecting brow ridge, strong postorbital constriction, nuchal torus, angled occiput (between the occipital and nuchal planes), and spongy bone development at the cranial base. Most of these features can be found on the juvenile *H. erectus* specimen (WT 15000) from East Africa.

If the date of 1.81 million years ago is correct, the Modjokerto child is the oldest hominid that has been found so far in Asia. Given the very early date and the lack of distinct morphological features, this cranium could be from an earlier hominid.

MOHENJO DARO

Since the beginning of excavation at this complex of mounds in 1921–1922, Mohenjo Daro became the most famous site of the “Indus” or “Indus Valley civilization,” although the slightly earlier work at Harappa provided archaeologists with a type-site and the historical–cultural designation “Harappan.” Even today, the terms *Harappan* and *Harappan civilization* are used as synonyms for Indus (or Indus Valley) civilization and refer to remains at Mohenjo Daro and numerous other sites that share recognizable features with Harappa. In fact, during the Bronze Age (ca. 2600–1900 BC), hundreds of settlements (some of

them quite large) dotted the transborder region of northwestern India and eastern and southern Pakistan. Although each of these Bronze Age sites has its own story, each also shared a sophisticated and distinctive cultural tradition that continues to inspire archaeological research and impress visitors.

Years ago, scholars suggested that Mohenjo Daro and Harappa, the latter of which was located approximately 400 miles to the northeast of Mohenjo Daro, were twin capitals of an empire. More recent surveys and excavations indicate that Mohenjo Daro was instead one of a number of urban centers (including Ganweriwala, Rakhigarhi, Dholavira, and Harappa) that served as hubs, perhaps like city-states, in a vast network of local and long-distance trade, all of which depended on the region's agricultural productivity. Residents at Harappan sites, including Mohenjo Daro, kept many species of domesticated animals, and various crops were grown, with wheat and barley being especially important. There is no hard evidence of irrigation, like that found in Egypt and Mesopotamia, but it is possible that floods destroyed such tangible remains or that the people of Mohenjo Daro used less elaborate systems to divert water. This Harappan economic network, which was concentrated in the alluvial plains of the Indus River and its tributaries, covered an area of at least 250,000 square miles and, at least in size, could be said to rival the territories united by rulers of ancient Egypt and Mesopotamia. The lack of historical accounts from this period and region makes it impossible to describe the political organization that created or protected this territory or to explain precisely how a major site such as Mohenjo Daro fits into the whole picture.

Mohenjo Daro itself is located in southcentral Pakistan's Sind province, on the west side of the Indus River, whose nearest branch is now located approximately 3 miles east of the site. Over time, the artificial mounds (evidence of long-term occupation and extensive use of mud brick), large portions of which remain unexcavated, have been severely eroded and destroyed by Indus flooding. The ruins cover approximately 250 acres, and population estimates for the ancient city range from 20,000 to 35,000. As is the case at Harappa, heavy alluvium has covered ancient occupational deposits at Mohenjo Daro and makes it impossible to determine precisely the site's size and population, which might have been considerably larger than current estimates.

The name *Mohenjo Daro* is modern and is usually translated as "Mound of the Dead"; like all Harappan

sites, this city's ancient name is unknown. Mohenjo Daro is better preserved than Harappa, and its exposed remains are impressive in terms of the site's layout and the extent to which buildings have survived. The rising water table has made excavation of the site's earliest levels difficult and sometimes impossible, and the rising water table even threatens the survival of buried remains.

Although it does not show signs of a long development before the Mature Harappan era (between the 26th century and ca. 1900 BC), there was later occupation at Mohenjo Daro, although it ceased to be an urban center during the 20th century BC. Like other cities of the Indus Valley civilization, natural events (e.g., shifting river courses, catastrophic floods) probably account for this cultural decline. Nowadays, fewer scholars attempt to explain the rise and fall of these cities with reference to invasion and migration (e.g., the Aryan invasion).

Mohenjo Daro has witnessed a long history of excavation from the 1920s until more recent times. The current research on the Harappan civilization has raised questions about earlier interpretations (e.g., the nature and extent of defensive structures), but some of those views have stood the test of time. Broad horizontal exposure of ruins on both the high western mound (the so-called "citadel") and the lower town on the huge eastern mound indicate the existence of larger public buildings (e.g., the "Great Bath," the "Granary") and extensive blocks of residential areas (which include many two-story houses with stairways). The features that have made the name *Mohenjo Daro* famous include the lower city's grid or layout, with streets that divide the fired-brick houses into blocks and an elaborate system of drains, brick-lined wells, and private bathrooms. As a whole, the architecture reflects wealth and a detailed construction plan, although not enough of either to prevent the damage caused by catastrophic floods.

Like other cities in the Harappan realm, the affluent class of Mohenjo Daro acquired luxury products by exchanging with distant lands through a system of overland and maritime trade. Indeed, the Harappan traders and their partners abroad used a standard system of weights. Many kinds of crops were raised, and many animal species were kept, especially cattle. Mohenjo Daro also played an important role in the domestication of chickens. Valuable imports included gold, silver, copper, carnelian, lapis lazuli, and turquoise—the raw materials for metallurgists and

jewelers. Timber was brought in from the mountains, and cotton cloth was manufactured. Craftsmen of Mohenjo Daro used the potter's wheel and made small objects from elephant ivory and faience. Some terracotta figurines were used as toys, whereas others represented deities. Objects from the Indus Valley have turned up at distant sites in India and in Mesopotamia.

Excavations at Mohenjo Daro have recovered some sculptures in the round such as the famous steatite bust of a bearded man (perhaps a priest) and the equally famous bronze sculpture of a dancing girl. The greatest artistic accomplishment of the Harappans is seen in their small, square stamp seals (most of them carved out of steatite). These were used to show ownership and have been found in large numbers; they are the principal medium for the 4,000 short inscriptions in the still indecipherable Indus script. Although no temple has been identified at any Indus civilization site, insight into Harappan mythology and religion may be provided by some intaglio scenes on these steatite stamps, which display other plant, animal, and human figures.

The Indus civilization, and each of its component sites, is a virtual laboratory for the investigation of early political and economic centralization and decentralization. Sites such as Mohenjo Daro contain valuable data for studying continuity and change with a regional context in South Asia and beyond.

to an institutionalized religious form of life that is characterized by radical solitude and mortification. Although most often associated with great religious traditions of Judaism, Christianity, Hinduism, Islam, and Buddhism, elements of monasticism are also evident in other traditions. The basis of the phenomenon is captured in a Native American elder's words: "True wisdom is only found far away from people, out in great solitude, and it is not found in play, but only through suffering. Suffering and solitude open the human mind, and therefore [one] must seek wisdom alone."

The worldview of monasticism is the ideals of truth and purity. From this perspective, the ordinary world prevents individuals from reaching their spiritual potential, so that a separation is needed. Most commonly, the elements essential to this quest for spiritual perfection are (a) celibacy (i.e., the freedom from familial or physical impairments), (b) poverty (i.e., the relinquishment of comforts of the world), and (c) obedience to some other person, usually a teacher, leading to the surrender of one's own will. These facets of monasticism have fascinated anthropologists for some time, leading to a number of sociocultural interpretations for the motivation and functions of these institutions. For example, Robert Levy, Gananath Obeyesekere, and others have used their work in psychological analysis to explain motivations and cultural structures that underpin the monastic vocation in various cultures.

Monasticism is commonly divided into two types: cenobitic and eremitic. The cenobitic life is characterized by a communal form of existence and is the most common type. The eremitic life is characterized by the life of the hermits, who tend to live in solitude and rarely are in contact with other humans. Most monastic traditions have elements of both. However, the Christian tradition of the Desert Fathers, the contemporary Carthusians, and the Jain ascetics are most often cited as eremitic groups.

Institutionalized monastic traditions are found in Jainism, Buddhism, Taoism, Christianity, Islam, and Judaism. Monasticism was also an element in the Vestal Virgins of Rome, the Peruvian Virgins of the Sun, and the Therapeutae of Egypt. The development of monastic systems runs parallel to the development of state systems in world history and to the organization of full-time religious specialists and the concern with secularization of society. Each of the monastic traditions depends on a philosophy of dualism in

MONASTICISM

Monasticism, from the Greek root meaning "alone" (mono) and from the Latin *monachus* (monk), refers

which the world is viewed as corrupt, a burden, or evil. The element of the human that sets one apart from nature is commonly referred to as the soul. In the monastic philosophy, then, the soul must be purified from matter. The universal process of this dualistic opposition is one of bodily mortification and contemplation and study on spiritual things.

Hindu Tradition

The Hindu tradition of monasticism is often viewed as the oldest form of monasticism. The Sramanas (Sanskrit: “recluse”) gathered circa 1500 BC to study the Vedic and practiced bodily mortifications. Also present in Proto-Dravidian and Pre-Aryan areas, these groups developed eremitic styles as well. By 600 to 200 BC, the ashram was an institution primarily for eremitic sects in India.

With the rise of Jainism, the ashrams became organized monastic centers. Jainism, which is noted for its attention to self-denial and mortification, has been especially important in the Hindu monastic tradition. The early organizer, Mahavira, originally established centers of professed monks and nuns who were ministered to by the local laity. An important development was the rejection of the caste system by the Jains and the later general disinclination to allow nuns (especially among the Digamboras). The ascetic life of the Jain monk is that of a wanderer whose five vows are those of nonviolence, truthfulness, nonstealing, chastity (i.e., no dealings with gods, humans, or animals of the opposite sex), and being indifferent to all things experienced through the senses. There has never been a well-organized system of monasticism in Hindu outside of the empire of Baktashiyah in Turkey. Each ashram is independent of the others, allowing a monk/nun to enter and leave relatively easily from any ashram.

Buddhist Tradition

The development of Buddhist monasticism is directly related to the Gautama Buddha (ca. 560–480 BC). According to the Buddha, the perfection of the Hindu

way could be attained only through withdrawal from the world. Only those who dedicated themselves to the religious life could attain perfection or Nirvana. As with Jainism, Buddha chose to ignore caste differences and initially opposed the inclusion of nuns in the monastic endeavor. The original Sanga, or organization, was based on relative moderation of discipline and mortification and on a close relationship with the laity. The contemporary Theravada tradition of Southeast Asia is often viewed as an example of this form of monasticism.

Buddhism is a way of life that is essentially monastic in its ideal form. One can attain the perfection of life only by denying the reality of the world and seeking release in meditation. To strip dependency on the self, monks typically will beg for alms and food and will strive to develop the desired characteristics of humility and tranquility. Again, because Buddhist monasteries are also independent of one another, the

rule of the individual abbot varies from place to place. There is relative ease of movement for the monks from one monastery to another or back to the laity.

The levels of importance and dominance of Buddhism among the cultures of Southeast Asia are diverse. Buddhism has dominated life in some countries, such as Burma and Thailand, and in many countries all men are expected to spend some time in monastic enclosures. Buddhist monasticism probably reached a height of influence in Tibet, where monks composed more than a fifth of the population and the Dali Lama ruled the country for more than three centuries. In Ceylon, the local abbot also often served as the local secular judge. Some thousand years after the death of the Buddha, the Zen form of Chinese Japanese Buddhism became a defining revitalization movement in parts of Southeast Asia. Zen Buddhism, allegedly, a truer form of the Buddha's intention for the attainment of perfection, is characterized by rigorous disciplines of contemplation and scholarly pursuits.

Christian Traditions

Monasticism in the Western and Eastern Christian traditions is characterized by a great deal of organization. Although it has never been as dominant as a way of life as has Buddhist monasticism, it has played a very important role in cultural continuity and adaptations. Usually, it is traced to the antiseccular movements of the 3rd century AD and to St. Anthony in Egypt, whose form featured the desert anchorites. The Eastern tradition of monastic enclosure is attributed to St. Basil of Caesarea (379 AD) and his sister, St. Macrina the Younger, whereas the Western tradition is attributed to St. Benedict of Nursia (ca. 500). Each of these initial movements was based on a neo-Platonic philosophy of dualism and the withdrawal from the world to contemplate and attain holiness. Also noteworthy here is the fairly radical cultural relative equality of women in the monastic movements.

The spread of monasticism in the Byzantine Empire was rapid, following the establishment of Christianity. It was well established in the East by the 7th century AD and as far as Moscow by the 14th century. To the West, monastic communities were well in place by the 4th century AD in Gaul and by the 5th century in Ireland, Carthage, and Italy. By the early Middle Ages, monasticism had become a defining and powerful economic, political, and religious

entity in Europe, with many monasteries controlling land, labor, and commerce.

One of the most significant factors that separate Western monasticism from other monastic forms is the Rule of St. Benedict. Whereas St. Bruno established the Catholic eremitic tradition at Chartres, France (Carthusians), Benedict's monastic community at Monte Cassino, Italy, during the 5th and 6th centuries AD became the role model for highly organized and detailed ways of living that became a way of uniting most of the European monasteries. Individuals living according to this tradition vow perpetual chastity, poverty, and obedience to their abbot and also vow stability to the particular monastery. So, rather than the transitional monasticism of the other great traditions, monks of the Western church became institutionalized professionals and often were elevated to high offices within the Roman Catholic Church. The monks of the West labored in fields, illuminated manuscripts, and devoted themselves to lives of silence, prayer, and study. It was through this diligent regime that the first Western universities came about during the 13th century.

Unlike Buddhist traditions, the Christian traditions became quite popular and welcoming to women. The abbesses of these communities could often attain a great deal of power and prestige. The relative autonomy and access to some venues of learning provided many women with an alternative to their limited options as females in many European countries.

The power centralized in the large monastic communities often led to accumulation of great wealth and prestige. During the 14th and 15th centuries AD, St. Francis of Assisi and St. Dominic led monastic reform movements that attempted to renew poverty as a defining element of the monastic/communal life. Thus, the order of friars, or monks who are also involved with worldly daily life but who live a mendicant lifestyle, was formed. However, the Protestant reformation of the 15th and 16th centuries eradicated monasticism from Protestant areas. They were not reestablished into Protestantism until the Oxford movement of the 19th century in England and after World War II in Taizé, France.

Judaic and Islamic Traditions

Judaism and Islam have some elements of monasticism, but they have a much less dominant impact on their history. Withdrawal from the world is not necessary

to find salvation for either religion. In fact, an active engagement with the world is often viewed as a virtue. Muhammad stated that “there are no monks in Islam,” and except for some Sufi sects, the Sensui of Sudan, and the Sahara, this remains the case today. Similarly, Judaism has had some elements of monasticism during periods of stress and upheaval (e.g., the Essene community) but has never promulgated a separation of the person from the community.

Monasticism continues to be an important institution in the Christian, Buddhist, and Hindu cultures. The West experienced a resurgence of monastic vocations after World War II, and many monks had a vital role during the Vatican II reforms of the 1960s. Buddhist monasticism experienced a revival during the latter part of the 20th century as well, with a great deal of interest spurred by the persecution of monks in Tibet, China, and elsewhere. And although India has witnessed a great deal of industrialized development, the ascetic path remains an important socio-cultural institution for the many Hindus. In the area of anthropology, current scholarship includes psychological studies of monastic methods and motivations, the form and function of monasticism in defining culture stability and change, and the role of monasticism in religious consciousness.

Located in Northeast Asia between the Russian Federation and the People's Republic of China, landlocked Mongolia covers an area of roughly 1.6 million square kilometers. Vast steppe regions, mountain areas, and desert areas dominate the country's physical geography, and its continental climate yields long cold winters and brief summers. These basic ecological features have provided the foundation for past and present understandings of the history and culture of the area's peoples. Given the country's considerable size, its population is relatively small at approximately 2.5 million people. Fully 80% of the population is considered to be Khalkha Mongolian, with the second largest group, the Kazakhs, represented in much smaller numbers at 6%. Peoples identified as being of Mongolian descent, however, live beyond the country's political borders in neighboring regions to the north and south. Mongolian populations have been fluid, contracting and expanding across the region and varying with the time period under consideration: the pre-Mongol Empire, the Mongolian Empire, the Manchu-Qing period, or modern Mongolia. This situation is recognized by most anthropological work, which predominantly examines mobile pastoralism, genetic origins, cosmology and religion, social organization, and post-socialist transformations within a broad framework that does not necessarily limit itself to the borders of the modern Mongolian state.

With the establishment of the Communist-based Mongolian People's Republic in 1924, Russian and

Mongolian scholars trained in the Soviet tradition of ethnology dominated research throughout much of the 20th century. Anthropologists from the West gained greater access to research with the country's transition to a democratic system of government during the 1990s. Many research teams now conduct multiparty cooperative research with international teams such as the Joint Mongolian–Russian–American archaeological expeditions. Although a significant amount of research from scholars around the world has been conducted since this period, much of this work remains unpublished or available only in journal articles and online materials. Popular perceptions of Mongolia and its peoples have arguably been shaped by the country's most well-known historical figure, Chinggis (Genghis) Khan, and by the early expeditions into the region by explorers best exemplified by Roy Chapman Andrews (1884–1960). Andrews's expeditions in Central Asia for the American Museum of Natural History provided a wealth of archaeological and ethnographic data that still contribute to ongoing research.

Early anthropological work sought to identify and describe the various groups in the area, emphasizing cultural traits that would, on the one hand, distinguish these groups from each other and from the more sedentary peoples around them and, on the other, enable anthropologists to hypothesize their origins and the possibility of common ancestors. Archaeologists continue to examine material artifacts to help them uncover the different ethnic identities present on the Central and Inner Asian steppes. Physical and biological anthropologists, using genetic and morphological studies, are reassessing evolutionary frameworks for the earliest migrations of modern humans and later migration patterns and development within Asia and the Americas, underscoring the need for more complex understandings of migration. Language has also been used as a marker for differentiating the peoples of the steppe region. Placed within the Altaic language family, the Mongolic languages and their similarities in general structure, agglutination, and vowel harmony have been considered as evidence of the origins of and links between Altaic peoples and also been used to posit theories about shared ancestors or waves of migratory groups. Anthropological inquiries into the peoples of Mongolia have been prompted not only by questions about the population's genetic history but also by historical and contemporary research into the relationships

between the area's ecology and its peoples, especially their social practices. Research on Mongolian populations have also focused on the role of borders and boundaries, challenged stereotypes and assumptions held about pastoral peoples both within the discipline and in public perceptions, examined the relationship between ecology and social organization, and highlighted the sociopolitical dimensions of cultural change (particularly during recent years with the impact and aftermath of the socialist transformation).

One of the most well-known scholars associated with anthropological work in the region is Owen Lattimore (1900–1989). In his examination of the origins of differentiation between Inner Asian peoples, Lattimore questioned the barbarian–civilized dichotomy. This dichotomy was based partially on historical and archaeological data on Neolithic groups that were used to rank them in accordance with their perceived level of “advancement.” Lattimore preferred a theory that explained divergent political formations (the rise of the state) and economic strategies (the rise of irrigation and rice culture) based on ecological differences in the region. In his *Inner Asian Frontiers of China*, Lattimore presented the idea of “frontier zones” as an analytical framework for describing the peoples and their relations in the area. When described as zones, the permeable and fluid nature of interactions and relationships in these areas is underscored. Lattimore's work opened avenues for later scholars due to its emphasis on cultural exchange in opposition to a presumption of unilineal acculturative forces as others scholars had suggested up to that point. More recent work addresses the legacy of the primitive/barbarian typology as well as ideas of “peripherality” that continue to have strong social, economic, and political impacts for the peoples in this region. This work included, but was not limited to, issues of identity, processes related to urbanization, and development.

Archaeological evidence demonstrates that mobile herding has taken place across Mongolia's grasslands for at least 2,000 years. Pastoralists in Mongolia practice a complex form of pastoralism involving the herding of several different kinds of livestock across seasonal pastures. Our understandings of a mobile pastoral lifestyle in the region are based largely on which historical period these studies examined, where comparisons of the given situation were often made to an idealized form of pastoralism prior to the advent of new systems. Pastoralism is often treated as

belonging on a spectrum where one end is the ideal pure form (complete mobility), the middle is a combination of different strategies (seasonal pasturing and some agricultural activities), and the other end is total sedentarization of herders (with acculturative forces often given as the cause). Emphasis is frequently placed on the impact of political systems on the demography of these populations and on the ecology of the area. Ecologically based and so-called culturally based arguments present pastoral and sedentary lifestyles as antithetical to one another rather than recognizing possibilities for diversity within these strategies. One recent line of research suggests that these systems' effects, although varied and of differing time depths, demonstrate the flexibility and compatibility of mobile pastoralism with a variety of political and economic systems. As such, mobile pastoralism should be considered as a strategy fully compatible with circumstances on the steppes today.

Debates over the processes and impact of sedentarization and acculturation coexist with debates over colonization and modernization in the entire region. Colonization by the Japanese in northern China and

the political and cultural domination of Mongolia by the Soviet Union contributed to population movements that affected not only the ecology but also the structure of people's lives. Descriptions of Mongolian social structure as it existed during the pre-Communist period focused on patrilineal descent and patron-client relationships as dominant forms of social organization. During the Communist period in Mongolia, kinship structure as the basis of social organization became less significant. As production teams of nonkin established by the government became more integrated, relations with kin outside became less important in terms of pastoral production. Kinship ties remained important to procure goods and services unavailable in rural areas so as to ensure the survival of the household. Within the household unit, its operations, division of labor, and ordering of space remained much the same. During the post-Soviet era of privatization, social relationships have changed and scholars are placing greater emphasis on the use of networks to describe social relations within and between pastoral groups, focusing on local ideas of herding groups (*ail*) to examine relationships between kin and relations based on

economic interaction, on use of pasturelands, and on friendship. Structural reforms put in place after the fall of communism also created new conditions that prompted a reevaluation of pastoralism in the area. Recent work focuses on indigenous notions of land use and their interplay with political and legal frameworks and on the larger issue of sustainable pastoral development. Anthropologists have pointed to the incompatibility of notions of land privatization with traditional notions of land ownership described by one scholar as “custodial.” Current land law in Mongolia supports public ownership of pastureland. Continuing challenges to pastoral lifestyles have spurred anthropologists to examine both local and global dimensions of political economy and how these often adversely affect cultural norms and values.

Research on religion in Mongolia tends to focus on shamanism, Buddhism, or a specific combination of Buddhist and shamanistic traditions. Shamanism or traces of shamanistic traditions are found throughout Turkic, Mongolian, and Siberian peoples, and researchers have emphasized a general similarity of features within the shamanistic practices in the area (part of a larger academic debate over the universality of shamanistic traditions). This amalgamation of Buddhism and shamanistic traditions is of particular interest to regional scholars interested in placing shamanism in relation to what they see as later traditions—Buddhism, Islam, and (to a lesser extent) Christianity. Research has shown a general resurgence of interest with the change in government. Mongolian concepts about nature are described as an active relationship where nature is conceived as complementary to, and not subordinate to, humans. Many objects in nature are considered to have spirits and relationships with these objects that are described in ways similar to those of human interactions. One example of shamanistic elements, whose survival during various periods may be linked partially to their incorporation into Buddhism, is the stone cairns (*oboos*) and rituals performed around them. They received much scholarly attention in part because these enactments highlight the relationship between humans and the spiritual world—one of responsibility to maintain a balance with nature. This relationship entails an obligation to spiritual authorities similar to that of secular authorities and the maintenance of good relations with the spiritual ones to ensure prosperity. In both social order and indigenous notions of land rights, we can observe these ongoing and often reformulated meanings.

In spite of the marked political, economic, and social transitions in Mongolian history, the preceding themes of religion, social relations, and pastoralism remain a significant part of ongoing research. The upheavals of the postsocialist transformation have reinvigorated the study of earlier models and well-established themes about the area and its peoples, revealing a richer and more complex set of processes that will continue to provide fertile ground for new research.

MONKEY TRIAL [1925]

On July 10, 1925, a high school biology teacher, John T. Scopes of Dayton, Tennessee, was charged in court with teaching evolution in violation of the Butler Act, a law recently passed by the Tennessee State Assembly that made it an offense to teach “any theory that denies the . . . Divine Creation of man.” The “Monkey Trial” attracted worldwide attention, filling the

newspapers for weeks as two of the leading lawyers of the day, William Jennings Bryan for the prosecution and Clarence Darrow for the defense, battled it out in the stifling Dayton courtroom. Once the trial was over, it was replayed in books, movies, and plays, being immortalized most memorably in only slightly fictionalized form by the 1960 Stanley Kramer film *Inherit the Wind*. Inevitably, the facts of the trial became lost in a haze of mythology.

In the popular myth, Scopes was represented as an innocent victim and the trial itself was represented as an unequivocal triumph of science over religion. Darrow was portrayed as the winner, and Bryan died of a broken heart shortly after losing. The facts are different. Scopes, a substitute teacher with a strong interest in the freedom of expression but no particular attachment to evolutionary theory, had volunteered at the prompting of the American Civil Liberties Union to participate in a deliberate test of the Butler Act. Indeed, it was Scopes himself who had betrayed his actions to the authorities. The case actually was won by the prosecution. However, the judge did not allow the merits of evolution versus creation to be debated in the courtroom, instead restricting argument to whether the law as written had actually been broken—and of course it had been. Although Bryan did die not long after winning the case, he died not from sorrow but rather from complications of diabetes.

Still, the importance of the Monkey Trial lay far less in its legal aspects than in the realm of public perception. Both Bryan and Darrow used every ploy possible in arguing their sides, and even though Scopes admitted breaking the law and was fined \$100 at the time (the conviction was later overturned on a technicality, and the state did not see fit to return to court), the cross-examination on both sides yielded the material for high drama. In the court of public opinion, reinforced by continuing media coverage, there was little doubt that Scopes and Darrow had won. All in all,

then, the case turned out to be a Pyrrhic victory for the creationist side. Nonetheless, the Scopes Monkey Trial did not lay to rest the matter of teaching evolution versus creationism. Activist fundamentalists in Mississippi and Arkansas soon passed bills similar to the Butler Act, which itself was not repealed until 1967. Another trial, “Scopes II,” was to follow in Arkansas in 1981, although this time the finding was in favor of the opponents of “creation science.” The issue has not gone away and seems unlikely to do so any time soon.

MONKEYS, NEW WORLD

New World monkeys (NWMs), also known as platyrrhines, live in tropical forest environments from

southern Mexico down through South America. The name *platyrrhine* comes from the broad, flat, external nose characteristic of this group of primates. There are more than 50 species of NWMs, all of which are predominantly arboreal and herbivorous. NWMs are divided into two families: Atelidae and Cebidae.

The first family, Atelidae, is divided into three subfamilies: Atelinae, Callicebinae, and Pitheciinae. The four genera of Atelinae (howling monkeys, spider monkeys, woolly monkeys, and woolly spider monkeys) are the largest of the NWMs, each weighing approximately 10 kilograms. All members have long, grasping, prehensile tails that can be used as a fifth limb. The second subfamily, Callicebinae, has only one member, *Callicebus* (titi monkeys). Titi monkeys are monogamous and eat mostly fruits, but they also eat leaves and insects. The third subfamily, Pitheciinae, is composed of three genera: *Cacajao*, *Chiropotes*, and *Pithecia*. Pitheciines are known for their strong teeth and the ability to bite through the outer coverings of fruits and seeds that are generally too hard for other monkeys to open.

The second family, Cebidae, is composed of four subfamilies: Aotinae, Callitrichinae, Cebinae, and

Incertae sedis. Like the Atelidae, some members of this family have prehensile tails. However, cebids have larger brains and more rounded, globular heads than do atelids. The first subfamily, Aotinae, has one genus, *Aotus*, commonly known as owl or night monkeys. Owl monkeys are the only nocturnal higher primate. As a result, they have the largest eye sockets of any anthropoid (higher primate). Individuals in the second subfamily, Callitrichinae, are the smallest NWMs. Callitrichines (tamarins, marmosets, and Goeldi's monkeys) have derived claws (instead of nails) that enable them to cling to tree trunks while feeding. In the third subfamily, Cebinae, there are two genera: *Cebus* (capuchins) and *Saimiri* (squirrel monkeys). These two monkeys are the most omnivorous, as well as the most well-known, NWMs. In addition, there are at least a couple dozen NWMs that are extinct, many belonging to uncertain taxonomic positions grouped as *I. sedis*.

The evolutionary history of the NWMs extends back approximately 30 million years to the ancestral platyrrhines, who may have reached the New World by rafting across the Atlantic Ocean from Africa. One of the oldest platyrrhine fossils is the Oligocene primate *Branisella*.

Today, many NWMs are endangered, especially some of the callitrichines. Although some of the larger species are hunted, deforestation and popularity as pets generally pose the biggest threats to many NWM species. Woolly spider monkeys are one of the most critically endangered primates. Their numbers dropped from 400,000 when Europeans first arrived in South America to 700 in 1996. However, there is hope for some NWMs such as golden lion tamarins, which are a critically endangered species that, through captive breeding programs, have been reintroduced to the wild successfully and are slowly creeping back from the edge of extinction.

MONKEYS, OLD WORLD

Old World monkeys (OWMs) are one of two major groups of monkeys, consisting of all primates belonging to the family Cercopithecidae. The family is composed of 18 genera and approximately 90 species, including baboons, colobines, guenons, and macaques.

OWMs are found throughout large portions of Africa and Asia, living in a wide range of habitats. They range from the savannas of Africa, to the tropical rain forests of Indonesia, to the snowy regions of Japan. Most OWMs are arboreal (tree dwellers), whereas some are terrestrial (ground dwellers). OWMs are nearly completely diurnal, meaning that they are active during daylight hours. Group structures among OWMs vary greatly. Most species live in social groups that consist of several adult males and females with their offspring.

Certain physical traits characterize OWMs. They are medium to large primates with body sizes ranging from 1 to 40 kilograms. They do not possess a prehensile tail like the other major group of monkeys (New World monkeys). OWMs' forelimbs are shorter than their hindlimbs and are characterized by narrow elbow joints. They are quadrupedal animals, meaning that they use all four limbs to locomote. OWMs have a narrow nose with a narrow palate. They also have four cusps on their molars that form two parallel ridges called bilophodont. Most species of OWMs have special sitting pads on their behinds called ischial callosities. In addition, many species are sexually dimorphic in body

size, meaning that the males are larger than the females of the same species.

The earliest fossil evidence of OWMs comes from remains of the family Victoriapithecidae and dates to the early Miocene (approximately 20 million years ago) in Africa. The family Cercopithecidae is divided into two distinct subfamilies based on features related to dietary adaptations. The first subfamily, Cercopithecinae, is composed of guenons and papionins. The latter group includes baboons, mangabeys, and macaques. The cercopithecines are omnivorous and have cheek pouches in which they can store food temporarily. Guenons, baboons, and mangabeys are exclusive to Africa. Macaques, on the other hand, are found predominantly in Asia. The second subfamily, Colobinae, is divided geographically. The colobines in Africa are referred to as colobus monkeys, whereas those in Asia are referred to as langurs or leaf monkeys. This is because their diets consist nearly entirely of leaves and unripe fruits and nuts. As such, they have a highly specialized, cow-like stomach that allows them to digest the cellulose in leaves.

De Brazza's monkeys (*Cercopithecus neglectus*) are one of the more recognizable guenons due to their unique facial hair and white beard. Some well-known papionin species include the sometimes snow-dwelling and hot spring-bathing Japanese macaques (*Macaca fuscata*) and brightly colored mandrills (*Mandrillus sphinx*). Long-haired Eastern black-and-white colobus monkeys (*Colobus guereza*) are notable African colobines. Most well known among the Asian leaf monkeys are the well-studied Hanuman langurs (*Semnopithecus entellus*) from India and the very large-nosed proboscis monkeys (*Nasalis larvatus*) of

many of the species to enter into monogamous relationships. For example, monogamous male parent birds care for the young by watching for danger (willow ptarmigans) or defending a territory with a nest cavity (eastern bluebirds), whereas his mate collects the food to feed the offspring. Male birds are involved further in most passerines, where they feed brooding females and/or help to feed the young. In herons, egrets, some woodpeckers, and others, males not only provide food for the young but also share in incubation.

On the contrary, for species whose males contribute little or nothing to rearing the young, females are very choosy in selecting the best mates. Males of these species compete to be chosen and are not themselves choosy. Females of these species, because of their biological ability to produce only a limited number of offspring, prefer mating with only the best males. From the male point of view, mating many times and with many females increases the chances of producing surviving offspring. Therefore, males must invest their energy to make themselves more attractive and appealing to as many females as possible. For example, the magnificently tailed peacock's elaborate train does nothing to enhance survival but is necessary for attracting mates.

The monogamous "bond" may vary from a single season to a lifetime. For example, most of the birds seem to form a monogamous bond that lasts from as short a period as single nesting (house wrens) to as long as a lifetime (albatrosses, petrels, swans, geese, eagles, and some owls and parrots). In a similar fashion, many monogamous animals pair for a season, but some (e.g., gibbons) pair for a lifetime.

During recent years, many ornithologists and behavioral ecologists began to view monogamy as part of a "mixed" reproductive strategy, that is, where matings may occur outside the primary pair bond but both members of the pair still contribute substantially only to the care and feeding of the young from their own nest. Some species are viewed to be "facultatively" monogamous; that is, they are monogamous due to certain environmental constraints. Once these constraints are removed or altered, they would typically exhibit some other form of mating system such

MONOGAMY

Monogamy refers to the norm or condition of a single male mating with a single female by forming a "pair bond," with both defending territory and caring for the young. The need to care for the young necessitates

as polygyny (one male mating with more than one female) or promiscuity (mating without forming pair bonds). For example, North American dabbling ducks are considered to be monogamous only due to the inability on the part of males to monopolize more than one female. These ducks breed synchronously, and their populations typically contain more males than females.

Prairie voles (*Microtus ochrogaster*) are among a select 5% of mammals that are habitually monogamous. Once they have mated, the males “fall in love” and stay close to their partners, protecting them, helping them raise offspring. Their close cousins, the meadow voles (*Microtus pennsylvanicus*), however, mate with multiple partners and pay little attention to subsequent offspring. When researchers alter the behavior of meadow voles by manipulating a single gene—*vasopressin receptor*—meadow voles become as monogamous as prairie voles.

Among human populations, monogamy stipulates that a man can marry only one woman at any one time in his life. It is essentially a social norm or a cultural custom. Even though various forms of marriages have been practiced through the generations, monogamy has emerged to become law in some countries today, such that the legal registration of more than one wife becomes a violation. Nonetheless, there are still several nations that prefer polygamy. For example, a worldwide ethnographic survey of 849 human societies showed 708 whose customs are polygynous (more than one wife), 4 whose customs are polyandrous (more than one husband), and 137 whose customs are monogamous. Even among those monogamous societies, a considerable number of married men and women tend to have sexual relationships with individuals outside their marriages. In her study on *Adultery*, Annette Lawson noted that various researchers arrived at a general consensus that (a) approximately one quarter to one half of married women have at least one lover after they are married in any given marriage and (b) married men stray more often than married women—perhaps 50 to 65% by 40 years of age. Similarly, Maggie Scarf thought that most experts estimate some 50 to 65% of husbands and some 45 to 55% of wives to be extramaritally involved by 40 years of age. Peggy Vaughan echoed that 60% of men and 40% of women are likely to have extramarital affairs. The significance of these figures is even higher when the total number of marriages involved is considered because it is

unlikely that all of the men and women having affairs happen to be married to each other. Vaughan observed, “If even half of the women having affairs (or 20 percent) are married to men *not* included in the 60 percent having affairs, then at least one partner will have an affair in approximately 80 percent of all marriages. With this many marriages affected, it’s unreasonable to think affairs are due *only* to the failures and shortcomings of individual husbands or wives.” Therefore, these scholars argue that the irony of the “monogamy myth” (a belief system that most people are monogamous and that only a few “bad” or “weak” people have extramarital affairs) is that it prevents societies from dealing with the issues that need to be addressed to make monogamy a more attainable goal for everyone.

Some studies suggest a new term, *serial monogamy*, to denote the practice of restricting sexual contact to a single partner (married or not) for a limited period of time and then ending that relationship before beginning another (although in practice there may be a brief overlapping time period). On the other hand, some have broadened the scope of the term *monogamy* to mean confining a sexual relationship to one other person even in the absence of a legal status of marriage (e.g., an unmarried heterosexual couple, a homosexual couple in a jurisdiction that does not recognize marriage between homosexual persons). Monogamy in this sense is recommended by health professionals discussing safer sex practices.

MONTAGU, ASHLEY (1905–1999)

Some might consider Ashley Montagu to be the original sociobiologist, but either they misunderstand the subject or they misunderstand the man. Actually, many of his numerous publications were critical analyses exposing the pseudobiology underlying sociopolitical issues such as racism, sexism, and ageism as well as more general questions about human nature, the nature–nurture controversy, and war and peace. For example, Montagu edited a volume of critiques called *Sociobiology Examined* (1980). Likewise, he was critical of any attempt to rationalize inequality on biological grounds, including eugenics and ideas about the biological basis of criminality. He was a prolific author and/or editor of more than 80 books, and he wrote hundreds of articles. Moreover, many of these publications addressed a general audience as well as an academic one. Thus, he was a pioneer in the arena of public anthropology, often as a penetrating social critic. For instance, he contributed a regular column to the *Ladies Home Journal*. These publications reflect an unparalleled breadth and diversity of scientific interests without sacrificing depth and accuracy, distinguishing him as a rare Renaissance scholar of the 20th century.

Montagu was born in London in 1905. In 1922, he entered the University College of London to study psychology and anthropology, with courses in the latter subject by Grafton Elliot Smith. Subsequently, he pursued social anthropology at the London School of Economics with Bronislaw Malinowski, Charles Seligman, and others. As the first student of Malinowski, his teacher's functionalism is apparent in some of Montagu's writings. (Fellow students included E. Evans-Pritchard and Raymond Firth.) Next, Montagu studied cultural anthropology at Columbia University with Franz Boas and Ruth Benedict. Boas's influence on Montagu's ideas about race is also apparent. Montagu's doctorate was completed in 1937 with a dissertation on concepts of sexuality and reproduction among Australian Aborigines. Accordingly, Montagu emerged as an anthropologist during the second and third decades of the 20th century as anthropology itself emerged as a scientific and academic profession and at two universities that were primary paradigmatic centers.

Never limited to anthropology, Montagu's omnibus interests and contributions spanned anthropology,

biology, history, philosophy, psychology, and sociology. This is also reflected in his friendship with other great individuals, including Albert Einstein, Theodosius Dobzhansky, Sir Julian Huxley, Sir Arthur Keith, Bertrand Russell, and Benjamin Spock. By working for most of his life outside universities with their disciplinary compartmentalization of knowledge, he was able to avoid the arbitrary specialization and reductionism that so often stifle other careers, not to mention understanding itself.

Montagu found academic employment at New York University (1931–1938), the Hahnemann Medical College and Hospital in Philadelphia (1938–1949), and Rutgers University (1949–1955). However, in a public lecture, some blunt criticisms of Senator Joe McCarthy's Communist witch hunts did not endear him to some administrators at Rutgers, and he was fired in 1956. Also, Montagu resigned from the American Association of Physical Anthropologists (AAPA) in 1953 and from the American Anthropological Association in 1955 due to the inaction of these organizations in the face of the House Un-American Activities Committee that persecuted him. After Rutgers, Montagu never held a regular teaching post. However, he did lecture in various positions, including the New School for Social Research (1931–1959), Harvard University (1945), the University of California, Santa Barbara (1962), and Princeton University (1978–1983).

Throughout his life, Montagu was a staunch critic of race as a biological idea and of the social phenomenon of racism as well as an advocate of racial equality and integration. In part, this reflects his recurrent personal experience with anti-Semitism throughout his life. For example, Montagu even changed his name from Israel Ehrenberg to avert some of the prejudice. The Federal Bureau of Investigation investigated Montagu off and on from the early 1950s into the late 1970s on the assumption that his ideas and actions against racism, his support of civil rights, and his views against war and for peace might be subversive. There was never any evidence that Montagu had any association with communism or socialism or, for that matter, that his work was even influenced by Marxism. Also, by persistently criticizing ideas about race that were current in early physical anthropology, Montagu alienated establishment personages such as Ales Hrdlicka of the Smithsonian Institution and Earnest Hooton of Harvard University. In 1939, Montagu introduced a motion at the

annual convention of the AAPA asserting that science provided no basis for discrimination based on race, religion, or language, but it was rejected. Nevertheless, eventually Montagu's ideas won out, as evidenced in his book *Man's Most Dangerous Myth: The Fallacy of Race*. This classic was first published in 1942 and was revised in a sixth edition in 1996. Another indication that he won the battle is his 1951 book *Statement on Race* related to his collaborative work with UNESCO. Montagu was not simply being politically correct (or for some, politically incorrect); rather, he was being rigorously scientific, often more so than his opponents in heated exchanges in print and at the annual meetings of the AAPA. At the same time, Montagu's research and writings about race and racism certainly challenged the status quo of American society during the 1940s and beyond.

The genius of Montagu as a didactic scholar and writer, as well as his acute sociopolitical relevance, is mirrored in the marvelous titles of his books, many of which he edited, such as *On Being Human* (1950), *Darwin, Competition, and Cooperation* (1952), *The Natural Superiority of Women* (1953), *Education and Human Relations* (1958), *Prenatal Influences* (1961), *Dolphins in History* (with John Lilly, 1963), *Up the Ivy* (1966), *The Anatomy of Swearing* (1967), *The Concept of the Primitive* (1968), *The American Way of Life* (1970), *The Elephant Man: A Study in Human Dignity* (1971), *Immortality, Religion, and Morals* (1971), *Touching: The Human Significance of Skin* (1971), *The Endangered Environment* (1974), *Race and IQ* (1975), *The Nature of Human Aggression* (1976), *Learning Non-Aggression* (1978), *Growing Young* (1981), *The Dehumanization of Man* (with Floyd Matson, 1983), *Science and Creationism* (1984), and *The Peace of the World* (1988). In 1980, one of his own books became the basis for David Lynch's celebrated movie *The Elephant Man*. Another one, *The Natural Superiority of Women*, remains a classic in feminism and gender studies. These books reflect Montagu's dedication to the adventure of ideas, as Alfred North Whitehead phrased it.

At the same time, Montagu regularly contributed significant purely academic works as well, including a monograph on the pioneering comparative primate anatomist Edward Tyson in 1943. Montagu also published a comprehensive and authoritative textbook, *Introduction to Physical Anthropology* (1945, 1951, and 1960 editions), which was widely used for decades and set a standard for successors. In particular, Montagu

was a proponent of the concept of neoteny, that is, the theory that human evolution selected for the retention of a prolonged period of infant dependency and maturation that allowed for educability and in turn contributed to the plasticity and adaptability of *Homo sapiens*. This was a central part of his book *Growing Young*. On the perennial issue of nature versus nurture, Montagu pursued an interactionist position, viewing the individual and group as a product of the interplay of their distinctive biology, culture, and history. He celebrated human potential and the opportunity for the individual to realize it instead of any simplistic biological or genetic determinism and constraints. Montagu also pioneered in studying evolutionary, cultural, and other aspects of aggression, war, nonviolence, peace, and cooperation. Such contributions were officially recognized by the AAPA in 1994 when it presented Montagu with the Charles Darwin Award for Lifetime Achievement.

Clearly, Montagu was an idealist, a humanist, a moralist, a liberal, and an internationalist—all in the best sense of the terms. His positions were not simply rhetorical; he also put them into practice, for example, in protesting the war in Vietnam in various ways. Also, he was a member of many liberal organizations and an ardent supporter of civil rights for African Americans, Native Americans, women, and others. He was a persistent voice of rationality in a society that was often dangerously irrational and unjust. His professionalism, scholarship, and activism led to appearances as a guest on television programs such as Johnny Carson's *Tonight Show* and the *Phil Donahue Show*. Like Margaret Mead, he played a prominent role in public anthropology.

Montagu died at 94 years of age in 1999 in Princeton, New Jersey. However, the substantial body of scientific, scholarly, and public works that he created have not died; they are as relevant today as they ever were, considering the many elemental and perennial questions he addressed.

MONTAIGNE, MICHEL EYQUEM DE (1533–1592)

Michel Eyquem de Montaigne was influential as a Renaissance courtier during the reign of Charles IX and, especially, as the author of *Essais*, through which he introduced a new literary form impressive for personal candor and humane skepticism.

Montaigne was born on the family estate Château de Montaigne in Perigord near Bordeaux, France. His father was a wealthy merchant who purchased the titled nobility and seigneurie of Montaigne. His mother was of Spanish Jewish ancestry, although her family had earlier converted to Catholicism. Montaigne spoke Latin as his principal tongue until 6 years of age, when he was enrolled at the nearby Collège de Guyenne. It is believed that he later studied law at Toulouse until 1557, when he became a *conseiller de parlement* in Bordeaux and entered into a close friendship with Etienne Boétie. Boétie's death in 1563 affected Montaigne profoundly. In 1565, he married Françoise de La Chassaigne, and the couple had six children, of whom only one, Lenore, survived to adulthood. In 1568, Montaigne's father died and he inherited the Château de Montaigne.

Montaigne's first major work was a translation—at the request of his father—of Raymond Sebond's *Theologia naturalis*. He then edited Boétie's works and resigned from his judicial post in 1571 to begin his *Essais* in the comfort of his Château library, with the first edition being published in 1580.

Montaigne's retirement was affected by troubles with kidney stones. In 1580–1581, this ailment caused him to seek treatment in France, Germany, Austria, Switzerland, and Italy. Journals from these travels were later published in 1774 as the *Travel Journal*. In retirement, he was also an important figure in the religious wars because his status as a devout but moderate Catholic engendered unique bilateral trust, as was evident in his mediations between the Catholic King Henry III and the Protestant Henry of Navarre (who eventually named Montaigne a gentleman of his chamber). While visiting Rome in 1581, he learned of his election as the mayor of Bordeaux, to which he returned to serve until 1585, again moderating during a period of religious strife and plague.

Montaigne continued his *Essais*, and in 1588 he met the writer Marie de Gournay, whom he took on as his *filles d'alliance*. De Gournay published Montaigne's works posthumously. Also in 1588, while visiting Paris, he was briefly jailed in the Bastille on suspicion of agency for Navarre. On the assassination of King Henry III in 1589, he helped to sustain Bordelaise loyalties to Navarre (who subsequently became King Henry IV of France and Navarre). Montaigne died in 1592 at the family château and was buried with full Catholic rites and a unique legacy of literary, philosophical, diplomatic, and theological humanism.

MONTE VERDE

For decades, there has been a consensus on the migration of people through the Americas. Some 12,000 years ago, as the end of the last Ice Age approached, big game hunters followed mammoth and caribou from Siberia across the Bering Land Bridge into

North America. These earliest people, called Paleoindians, settled into the interior plains of North America between 11,500 and 11,000 years ago, and from there they spread across North America and southward to the southern tip of South America following diminishing game reserves for the next 1,000 years. This Clovis model was named for a site near Clovis, New Mexico, where these hunters' distinctive leaf-shaped spear points were first discovered in 1932. New finds and new methods of dating archaeological materials not only have opened this theory to debate but have eliminated it as a possibility altogether.

After a long and bitter debate, archaeologists have agreed that there is evidence that humans reached southern Chile at least 12,500 years ago, more than 1,000 years before Clovis, the previous benchmark for human habitation in the Americas.

Monte Verde, the Chilean site, is located on the bank of Chinchihuapi Creek in wooded foothills approximately 30 miles from the Pacific Ocean and 500 miles south of Santiago. An excavation team, led by Tom Dillehay of the University of Kentucky, surveyed the site from 1977 to 1985. Another team of archaeologists investigated the site in 1997 and confirmed that Monte Verde does establish an earlier date for human habitation.

Monte Verde is an unusual site, providing materials never before found at early American excavations. It is common to find mostly bone and stone artifacts at Paleoindian sites, which tend to be in caves or are open-air sites where delicate artifacts are not preserved. In addition, Paleoindians generally were small nomadic bands of people, and small transient groups leave virtually no marks on the land, making them invisible to archaeologists. Monte Verde was encroached by a neighboring swamp soon after the inhabitants broke camp, covering the site in a layer of peat. With no oxygen present to decay materials, Monte Verde has yielded remnants of wood plank shelters covered with hides, animal meat, digging sticks, carved bone and tusk tools, grasses tied into ropes, hearths, human fecal remains, and a child's footprint. Dillehay has concluded that a group of 20 to 30 people occupied Monte Verde for perhaps a year before moving on.

More recently, a knoll several hundred feet away from Monte Verde has drawn some attention. A cursory excavation of the hill has yielded possible evidence of human habitation 20,000 years earlier

than Monte Verde. Rather than causing an upset, independent archaeologists have verified the antiquity of the level. Dillehay and Mario Pino, of the Southern University of Chile in Valdivia, are planning to formally excavate the site in the near future.

Since the discovery and acceptance of Monte Verde, scattered sites from Wisconsin to Central and South America have indicated the presence of humans before 13,000 years ago. These discoveries are leading archaeologists to look for alternative theories about how and when people first arrived in the Americas.

The Yale University professor of political and social science William Sumner (1840–1910) coined the term *mores* from the Latin word *mos*, which is generally translated as “customs.” He described mores as a type of folkway that a group of people accepted as the unquestioned way in which they should live. Because people do not question their mores, mores regulate behavior and those who violate them receive extreme punishments. Humans crafted folkways and mores because they have basic needs. They adapted folkways that helped them to survive and gave up those that hurt their chance to survive. Mores determined how people acted, and tradition made the mores fixed and coercive. Sumner wrote that mores were so stable that only rulers could gradually change them. This made it useless to try to reform society. He also said that people made laws to enforce their mores. To describe mores in his book *Folkways*, Sumner used examples from all over the world, so that the book resembles many anthropological works of the early 20th century.

Mores relate to another term Sumner coined, *ethnocentrism*. He wrote that people do not even notice their mores until they come into contact with people who have different mores. Because people are born into a situation with mores already in place, they do not criticize their own mores but do criticize other people who have different mores.

In anthropology, the concept of mores mostly influenced psychological anthropologists in the United States, such as Clyde Kluckhohn (1905–1960) and Alfred Kroeber (1876–1960), in terms of how they understood the concept of culture. They said that culture had developed out of human needs but that once it was in place, it exerted power over people. Kluckhohn said that a group constantly discovers and invents new things but that only those who contribute to the group's survival or who promote psychological adjustment become part of the culture. Then the culture regulates every aspect of a person's life. Kluckhohn also said that once a way of doing something has become institutionalized, people resist changing or deviating from it.

The term *mores* has become a standard term in sociology, although nowadays most sociologists contrast mores with folkways rather than saying that mores are a type of folkway. They describe folkways as norms that are lightly sanctioned and describe mores as norms based on the core values of society. Thus, murderers, rapists, and child molesters violate some of the most important mores of the United States. Other violations of mores, such as stealing, would be less serious. Sociologists say that mores of the past have become folkways and that folkways have become mores. Furthermore, mores in one society are not mores in another society, and mores of members of subcultures of a culturally diverse society, such as the United States, differ. In general, mores have sanctions, so that a person who violates a more is subject to punishment such as imprisonment or even death. Mores can be further divided into prescriptive and proscriptive mores. Prescriptive mores tell people what they must do, whereas proscriptive mores tell people what they must not do. Common proscriptive mores in the world are not to practice cannibalism or incest. Such extreme mores are also called taboos.

MORGAN, ELAINE (1920–)

For the first 50 years of her life, Elaine Morgan (née Floyd) did not seem like someone who would be mentioned in an anthropology class, but 30 years after that it would be a rare introductory class on human evolution where at least one student did not ask about her ideas. Born in 1920 in Pontypridd, Wales, Morgan was good at school but leaned toward literature rather than science. She won an exhibition (scholarship) to Lady Margaret Hall, Oxford, where she studied English language and literature. After attending the university, she became a lecturer at the Workers' Education Association. During the early 1950s, she started freelance writing in newspapers and magazines and then began a lifelong career in writing for television, eventually becoming an award-winning writer of serials, documentaries, and adaptations.

After nearly 20 years in television, Morgan read Robert Ardrey's *African Genesis* and Desmond Morris's *The Naked Ape*, did not like what she read, and in reaction came up with her first book on human evolution using the "aquatic ape" idea she had first discovered in Morris's short writeup of the idea. The result, *The Descent of Woman*, was a huge success, at least in the popular arena, and was translated into nine languages. She continued in her successful television career but also followed up on her new aquatic ape work with a slew of articles and talks as well as four more books: *The Aquatic Ape* (1982), *The Scars of Evolution* (1990), *The Descent of the Child* (1994), and *The Aquatic Ape Hypothesis* (1997).

Morgan was also involved in a conference on the subject with both "pro" and "con" participants in 1987 and a resultant book (*The Aquatic Ape: Fact or*

Fiction?), a symposium on the aquatic ape theory at the annual meeting of the British Association for the Advancement of Science in 1992, and a BBC documentary in 1999.

Although Morgan's supporters, faced with people opposing her ideas, often make a bid for leniency and some sympathy based on her age, Morgan herself does not take that tack. She seems to enjoy the parry and thrust of debate. After meeting her during part of the filming of the BBC documentary, anthropologist Bernard Wood described Morgan, in her late 70s, as "a tiny doughty sparrow of a lady whose advanced years have not dimmed her, or her supporters' abilities to literally pin you against the wall so that she, or they, can make their point."

The next point Morgan is planning to make is on evolutionary biology in a forthcoming book titled *Darwin and the Left*.

MORGAN, LEWIS HENRY (1818–1881)

Lewis Henry Morgan was an influential 19th-century ethnologist who dedicated most of his career to kinship studies. He documented an extensive amount of valuable written and physical material on the Iroquoian culture. Morgan was born on November 21, 1818. He grew up in a farmhouse close to Aurora, New York, and enrolled at the Cayuga Academy. Afterward, he attended Union College, where he graduated in 1840. Morgan studied law, and in 1842 he was admitted to the bar. Because of conditions caused by a depression at that time, Morgan joined a group of individuals who called themselves the Grand

Order of the Iroquois. Their main purpose was to help create a society that would treat the Iroquois with more compassion and consideration.

In 1849–1850, Morgan collected information and cultural artifacts from the Seneca Iroquois of Tonawanda. He also obtained articles from the Six Nations reserve on the Grand River in southeastern Ontario. These included traditional ceremonial items, clothing and adornment, containers, transportation tools, war and hunting tools, cooking tools and food-stuff, a house model, containers, cradles and cradleboards, and other miscellaneous items. The Parker family significantly helped to recreate and explain the culture and use of the material objects. As a result, Morgan was able to produce extensive reports on the livelihood of the Seneca people. He gathered approximately 500 objects within the culture that were given to the Historical and Antiquarian Collection of the New York State Cabinet of Natural History.

Throughout his anthropological career, Morgan was best known for three of his books: *League of the Iroquois* (1851), *Systems of Consanguinity and Affinity of the Human Family* (1871), and *Ancient Society* (1877). Morgan researched the lives of the Iroquois on the Seneca more intensely within these books. He studied the social and organizational methods within their culture and focused on their customs and beliefs. This documentation of the Iroquois is believed to have been one of the first concrete scientific descriptions of the Iroquois culture.

Morgan's second book, *Systems of Sanguinity and Affinity of the Human Family*, concentrated on the origins of the American Indians. In 1865, Morgan discovered that American Indians of different language families used similar kinship terminology. He found that even though these tribes were of different and unique cultural backgrounds, they referred to members of their families in the same way. The father's brother would be called father, and the mother's sister would be called mother. The children of either parent's brother or sister would be referred to as brothers or sisters.

Even though Morgan had discovered these similarities, he undertook to find out whether these practices were consistent among all American Indians. From there, he wanted to determine whether this kinship terminology correlated with that of the system in Asia. His theory developed into the belief that the American Indians were actually of Asian origin. Morgan began his research. Over the course of

4 years, he traveled throughout the United States and Canada, where he documented information. He distributed questionnaires to collect data within the United States, India, Africa, and surrounding islands. The results showed him that the Tamil people of southern India used the same kinship terminology as the American Indians. Morgan considered this as proof that the American Indians were in fact of Asiatic origin.

Morgan continued to suggest that there was an explanation as to why families within these communities combined their titles of kinship such as calling a mother's sister "mother" and calling a father's brother "father." In *Ancient Society* (1964), he concluded that there must have been an "ancient existence of a consanguine family in which brothers and sisters intermarried in a group . . . and beyond this, in the remotest antiquity of mankind, lay promiscuous intercourse where no customs of marriage existed at all." Although Morgan's theory proved to be inaccurate, he was acknowledged for his extensive data collection and inquiry. This information was used for his book, *Systems of Consanguinity and Affinity of the Human Family*. Morgan gathered a very significant amount of information regarding his travels and experiences within these cultures unlike any other anthropologist from that time.

With origin on his mind, Morgan began to focus on biological and cultural evolution. *Ancient Society* was written to explain the process that cultures went through to evolve into civilized societies. He suggested that a society went through three main stages during its biological and cultural evolution. A culture began at the very bottom of existence as humans in savagery, then moved toward barbarism, and ultimately reached civilization.

Within savagery and barbarism, Morgan created three levels; lower status, middle status, and upper status. Morgan's theory rested on the assumption that through inventions, discoveries, and the growth of ideas, cultures evolved and progressed to the next stratum of human existence. Within the stratum of savagery, people relied on wild plants to survive. There was no working the land or animal domestication. Barbarism was defined by the initial use of agriculture. Civilization involved the use of the written word and the desire for property. In further detail, Morgan suggested that from barbarism, humankind was able to control subsistence use, and this allowed the continuation of the human species. From the

cultivation of plants and cereals and the domestication of animals, societies created an abundance of permanent subsistence and therefore reached civilization. Morgan continued to distinguish between primitive and civilized societies when he stated, in *Ancient Society*, that primitive society was "founded upon ties of kinship, and modern, or civil, society is organized upon the basis of property relations and territorial distinctions."

Morgan died in 1881. Some of his work had since been proven to be false and seen as Eurocentric, but he is still considered as an important anthropologist from his time. Through his timeless research, data collection, analysis, and work with the Iroquois, he is seen as one of the founding fathers of anthropology.

MORPHOLOGY VERSUS MOLECULES IN EVOLUTION

One of the first investigators of the "blood relationship" of organisms was George Henry Falkiner Nuttall. Early in the 20th century, Nuttall sought to demonstrate that the degree of similarity between animals in their blood serum proteins reflected their evolutionary closeness. He produced an antiserum to serum of one animal and combined it with another animal's blood serum, producing a precipitate. The more precipitate that formed, the greater the similarity (due to a greater number of antibody–antigen binding sites) and, consequently, the closer the supposed evolutionary relationship between the organisms

being compared. Nuttall also thought that the reaction rate reflected closeness of relatedness. He concluded in *Blood Immunity and Blood Relationship*, "If we accept the degree of blood reaction as an index of the degree of blood relationship within the Anthroidea, then we find that the Old World apes are more closely allied to man than are the New World apes, and this is exactly in accordance with the opinion expressed by Darwin." But for the most part, Nuttall's work went unrecognized for decades.

Perhaps the most influential publication of the early 1960s in the area of biochemistry and relatedness was Emile Zuckerkandl and Linus Pauling's 1962 chapter on fetal and adult hemoglobin. They compared human, gorilla, horse, and fish sequences and found that the fish was more dissimilar to the human than to the horse and that the gorilla was most similar to the human. Because this arrangement mirrored the morphologically based phylogeny of these taxa, Zuckerkandl and Pauling believed that their observations "can be understood at once if it is *assumed* that in the course of time the hemoglobin-chain genes duplicate, [and] that the descendants of the duplicate genes 'mutate away' from each other" (emphasis added). From this assumption, they concluded that "over-all similarity must be an expression of evolutionary history," with descendants "mutating away" and becoming "gradually more different from each other." That is, the more ancient a lineage, the more molecular difference its descendants will gradually accumulate. Consequently, evolutionary closeness became equated with molecular difference despite the fact that Zuckerkandl and Pauling's study did not justify assuming that "over-all similarity" is "an expression of evolutionary history," that difference always reflects the same directionality of change, or that molecular change accrues at a constant and gradual rate. Nevertheless, as Adalgisa Caccone and Jeffrey R. Powell wrote in 1989, "Virtually all molecular phylogenetic studies . . . have a major underlying assumption: The genetic similarity or difference among taxa is an indication of phylogenetic relatedness. Lineages that diverged more recently will be genetically more similar to one another than will be lineages with more ancient splits." Embrace the assumption and the rest may follow logically, but not necessarily biologically.

In 1966, Vincent Sarich and Allan Wilson began investigating primate evolutionary relationships using albumin, translating degree of reactivity between albumin and anti-albumin into "immunological

distance" (ID). An ID value of 1.0 meant "identical" (as in combining serum and antiserum of the same individual). The closer an ID value was to 1.0, the greater the overall molecular similarity and thus, by extension, the more closely related the taxa under study. As a "check" on the validity of this approach, Sarich and Wilson conceived the "test of reciprocity" (reversing whose serum or antiserum was used), which usually confirmed the initial finding. Because their arrangement of the primates agreed more with than it differed from the morphologically based pattern of primate relationships, they concluded that the "data are in qualitative agreement with the anatomical evidence, on the basis of which the apes, Old World monkeys, New World monkeys, prosimians, and nonprimates are placed in taxa which form a series of decreasing genetic relationship to man."

The following year, Sarich and Wilson argued that molecular change occurred at a constant rate among all major groups of primates and that, if the small difference between hominoid albumins reflected little molecular change, little time must have elapsed since the hominoid lineages separated. They claimed that because molecular change was constant, IDs represented a "molecular clock," which they calibrated on the fossil-based interpretation of when the Old World monkey and hominoid lineages supposedly split and then calculated that gibbons diverged approximately 10 million years ago, orangutans diverged approximately 8 million years ago, and humans and African apes diverged approximately 5 million years ago. The obvious implication was that fossils older than 5 million years, such as *Ramapithecus* (= *Sivapithecus*) from approximately 12 to 14 million-year-old deposits in Indo-Pakistan, could not, as their morphology indicated, be hominid. In 1971, while defending the correctness of the molecular clock, Sarich rejected as being of any phylogenetic significance the very morphology on which the clock was predicated.

But although all molecular systematists accepted the molecular assumption, M. Goodman and others did not embrace a constant molecular clock. Because Goodman accepted the paleontologically derived date of less than 14 million years ago for the hominid–ape split, he had to offer a different explanation for the small difference between hominoid albumins.

Although similar to other anthropoids in having hemochorial placentation, large-bodied hominoids have longer gestation periods. As such, Goodman argued, whereas in animals with hemochorial

placentation but short gestation periods parturition would occur before the mother's immune system could produce antibodies to any molecular differences in the fetus, in large-bodied hominoids the gestation period is long enough not only for maternal–fetal immunological incompatibility to build up but also for maternally produced antibodies to diffuse through the placenta and attack the fetus. Consequently, selection must have acted to reduce the possibility of maternal–fetal immune interaction by slowing down the rate of molecular change in hominoids with longer gestation periods.

Protein sequences were also used to determine evolutionary relationships. As mentioned earlier, Zuckerkandl and Pauling first sequenced hemoglobin in 1962. In 1973, A. E. Romero-Herrera and colleagues analyzed myoglobin sequences of various taxa. The most “parsimonious” arrangement of hominoids placed the gibbon closer than the orangutan to a human–African clade. The order of the gibbon and orangutan could be reversed only by invoking a more complicated scenario of hominoid myoglobin “evolution,” including specifying various “back-mutations” to the presumed primitive state.

But although protein sequences were seen by some, especially Zuckerkandl as late as 1987, as appropriate for analyzing evolutionary relationships, others thought that the “best” systematic information lay at a deeper “genetic” level. Because base differences at the third base position did not produce different amino acids, the concern was that demonstration of similarity in protein sequences could produce “false” phylogenies because the underlying nucleotide sequences could be different. The expectation (based on bacteria and inferred for metazoans) was a direct correlation between specific DNA sequences and specific genes. In addition, because DNA sequences are composed of thousands of bases, there was the appeal of a vast amount of supposedly phylogenetically relevant information. But because DNA sequencing, although possible by the late 1970s, was expensive and laborious, an alternative approach—DNA hybridization—was used.

The justification for using DNA hybridization as an approximation of overall DNA sequence similarity between different taxa lay in the fact that not only will two separated strands of DNA from the same individual reassociate (reanneal) via their complementary bases, but any two single strands of DNA from different taxa will attempt to recombine or hybridize at

complementary base positions. The more complementary sites between hybridized DNA strands, the more heat is needed to melt the bonds between them. From the molecular assumption followed the assumption that differences in melting temperatures reflected degrees of molecular similarity that reflected evolutionary relatedness. But because DNA hybridization relied on an assessment of overall similarity rather than the identity of sequences of bases, similar differences in melting temperatures obtained for different pairs of taxa might not be due to hybridization of the same regions of DNA. This is not a trivial concern because, DNA sequences, even if homologous, are not the same length in all animals, large-bodied hominoids included.

In 1968, R. J. Britten and D. E. Kohne first employed DNA hybridization in 1968 and found that the genomes of higher organisms—but not of bacteria or viruses—contained “hundreds of thousands of copies of DNA sequences” (repeated DNA) that not only represented a considerable portion of a genome but also were “trivial and permanently inert.” Only a small fraction of a genome was composed of apparently active or functional single-copy DNA. They also argued that theories of genomic change must be considered on two levels: the change in nucleotide sequence (gradually via point mutations) and the origin of new families of nucleotide sequences (suddenly via “saltatory replications”). The former explains only the “divergence of pre-existing families” of nucleotide sequences, whereas “saltatory replications of genes or gene fragments occurring at infrequent intervals during geologic history might have profound and perhaps delayed results on the course of evolution.” Although a model of “saltatory replication” is not embraced by molecular systematists, it poses a serious challenge to the “molecular assumption” and appears to have been borne out with the identification during the 1990s of the vertebrate *Hox-a-d* genes as replicates of the *Antennapedia* gene of fruit flies.

During the 1980s, Charles Sibley and Jon Ahlquist questioned previous DNA hybridization experiments due to the limited number of cross-hybridizations that were tested. This, they claimed, was the reason why certain evolutionary relationships could not be resolved. They made a point of the lack of resolution of the relationship between humans and African apes that, although based on little morphology, had become the favored molecular hypothesis. They also argued that one must create hybrids only with single-copy

DNA. And because DNA hybrid strands will link up only along complementary stretches of bases, there should be no question about homology.

Sibley and Ahlquist proposed a uniform average rate of genomic change (UAR), which they believed characterized molecular, and thus evolutionary, change in all taxa. By assuming a UAR, they also side-stepped the molecular clock debate. The power of DNA hybridization in “discovering” the phylogenetic relationships of organisms supposedly came from sampling entire genomes. Because an organism’s genome is composed of millions of nucleotides, the “law of large numbers” seemingly eliminated the problem of an analysis being thrown off by “false” similarities or parallelisms.

In 1983, Sibley and Ahlquist converted differences in melting temperatures for DNA hybrids into phylogenetic distances using a procedure called “average linkage,” which begins “by clustering the closest pair or pairs of taxa,” after which “one links the taxa which have the smallest average distance to any existing cluster” until “all taxa are linked.” The underlying assumption is that DNA hybridization “measures the net divergence between the homologous nucleotide sequences of the species being compared.”

Many aspects of Sibley and Ahlquist’s phylogenetic reconstructions of birds were consistent with theories of relatedness derived from study of morphology. But there were some significant differences, for instance, with regard to the broader phylogenetic relationships of, as well as the details of relatedness among, the flycatchers. However, by the 1980s, it was common practice, when molecular and the morphological phylogenies were in discord, to opt for the former. The molecular assumption demands that a molecular phylogeny be correct in its entirety, even if other information contradicts it.

The appeal of Sibley and Ahlquist’s “law of large numbers” and UAR was probably the reason why paleontologists finally gave in to the notion that when molecularly and morphologically based phylogenies were in conflict, the former had greater authority. But not all molecular systematists were convinced. Templeton, for instance, rejected DNA hybridization because one could not determine the polarity of the similarity and thus address the question: Is similarity due to distant or recent common ancestry? He favored studying actual nucleotide sequences. Sibley and Ahlquist countered that there was “no reason to expect data derived from base sequences to improve

on those from amino acid sequences, which have produced contradictory results.” Nevertheless, the role of DNA sequences in deciphering evolutionary relationships assumed special significance due to the supposed information content of nuclear DNA. As E. J. Bruce and F. J. Ayala wrote in 1979, “Information macromolecules—i.e., nucleic acids and proteins—document evolutionary history. . . . [Thus,] degrees of similarity in such macromolecules reflect, on the whole, degrees of phylogenetic propinquity.”

In 1979, W. M. Brown and colleagues found more difference between humans and a sampling of Old World monkeys in their mitochondrial (mt) DNA than in their nuclear DNA. Accepting the paleontologically estimated divergence between the human and Old World monkey lineages as more than 20 million years ago, they calculated that nucleotide substitutions occur 5 to 10 times more slowly in nuclear DNA than in mt DNA; that is, mt DNA “evolves” 5 to 10 times faster than nuclear DNA. From this, Brown and colleagues argued that mt DNA is better for studying evolutionary events that occurred “within the past 3–10 million years.” Although their data showed the fewest differences (interpreted as substitutions) between humans and chimpanzees, Brown and colleagues presented humans as being related to an African ape group. Given the molecular assumption, however, the data should have yielded a human–chimpanzee sister group, as M. Ruvolo and colleagues concluded from their 1991 analysis of mt DNA.

One assumption about mt DNA is that, because it is single-stranded, it is not subject to the complexities that occur through recombination of maternal and paternal DNA; it is supposed to be inherited clonally only through the maternal line. Another assumption is the existence of a “hotspot” (the “hypervariable zone”) in the D-looped configuration of mt DNA that is the primary site of molecular activity and, therefore, the source of evidence of evolutionary change. The introduction of paternal mt DNA into fertilized eggs has been reported, however, and according to Erika Hagelberg, there is increasing indication that mt DNA is not as exempt from paternal inheritance and recombination as was initially believed. Hagelberg also pointed out, in a 2003 article, that “there is no direct evidence of hypervariability,” although “most researchers believe that anomalous patterns of DNA substitution are best explained by mutation.” Indeed, “because the notion of hypervariability fits with the

received view of mt DNA clonality, anomalies are seldom questioned.”

Questions also arose concerning the comparisons of sequence data, especially with regard to alignment. Because compared DNA sequences are usually not the same length, decisions must be made about subdividing the shorter sequence to align its nucleotides with those of the longer sequence. Typically, sequence alignment is presented in the literature without justification and then is used in phylogenetic analysis. But as J. A. Lake warned in 1991, “The order of sequence alignment can bias the selection of tree topology.” In addition to assumptions of alignment are those of whether, for one or another sequence, bases were inserted or deleted or one base was substituted for another.

In 2003, in *What It Means to Be 98% Chimpanzee*, Jonathan Marks gave an example of these problems with DNA sequences from a human and an orangutan by showing three different ways in which their bases can be aligned. Of course, one must first assume that the 40 bases in the human sequence have homologous counterparts in the 54 bases in the orangutan sequence:

Human: CCTCCGCCGCGCCG CTCCGC GCCGC-
CGGGCA CGGCC CCGC

Orangutan: CC GTCGCCTCCGCCACGCCGCGC-
CACCGGGCCGGGCCGGCCCGGCCCGCCCCGC

Human: CCTCCGCCGCGCCGCT CCGCGCCGC-
CGGGCACGGCCCCGC

Orangutan: CCGTCGCCTCCGCCACGCCGCGC-
CACCGGGCCGGGCCGGCCCGGCCCGCCCCGC

Human: CCTCCGCCGCGCCG CT CCGCGCCGC-
CGGG CAC GGCC CCGC

Orangutan: CCGTCGCCTCCGCCACGCCGCGC-
CACCGGGCCGGGCCGGCCCGGCCCGCCCCGC

Marks commented,

The top one invokes five gaps and six base substitutions; the middle has only two gaps but nine base substitutions. And the bottom one has five gaps and only three base substitutions. The three pairs of sequences differ in the assumptions about which base in one species corresponds to which base in the other. While we might . . . choose the alignment that invokes the fewest inferred hypothetical evolutionary

events, we still have to decide whether a gap “equals” a substitution. Does the bottom one win because it has a total of only eight differences? Or might the middle one win because a gap should be considered rare and thereby “worth,” say, five base substitutions?

We cannot know which is “right,” and the one we choose will contain implicit information about what evolutionary events have occurred, which will in turn affect the amount of similarity we tally. How similar is this stretch of DNA between human and orangutan? There may be seven differences or there may be eleven differences, depending on how we decide the bases correspond to each other across the species—and that is, of course, assuming that a one-base gap is also equivalent to a five-base gap and to a base substitution.

In a more general sense the problem of taking *quantitative* estimates of difference between entities that differ in *quality* is prevalent throughout the genetic comparison of human and ape. The comparison of DNA sequences presupposes that there are corresponding, homologous sequences in both species, which of course there must be if such a comparison is actually being undertaken. But other measurements have shown that a chimpanzee cell has 10% more DNA than a human cell. . . . But how do you work that information into the comparison?

These concerns have not, however, been widely appreciated by molecular anthropologists, who portray the analysis of DNA sequences as neutral and objective but still use an assumption of relatedness to inform the way in which they analyze the sequences they have aligned according to certain assumptions. Exemplary is the 1997 multiple DNA sequence analysis by Ruvolo, who sought to resolve the supposed dilemma of which African ape humans are more closely related to by assuming that humans and African apes were indeed a clade and that the orangutan was its sister taxon. Consequently, whatever differences were found in the orangutan data had to be considered primitive relative to any similarities that were delineated between humans and one African ape or both African apes.

In using the popular parsimony-based phylogenetic computer program PAUP (phylogenetic analysis using parsimony), it is common practice to “root” a phylogenetic analysis in a taxon that is chosen as the primitive sister taxon or out-group. But although rooting any analysis in a particular taxon may be

necessary for the algorithm to “work,” this procedure artificially determines character polarity given that the taxon in which the tree is rooted is defined *a priori* as being primitive in its entirety. In turn, the taxa to which this taxon is the supposed primitive sister taxon are predetermined as being derived in whatever ways they differ from it.

This approach to analyzing nuclear DNA, mt DNA, and protein sequences (and most recently to hominoid morphology) presents its own set of problems. Consider the molecular assumption: Because molecular change is supposedly ongoing and accumulated in a succession of descendants, the degree of molecular similarity should reflect the antiquity or recency of lineage divergence. Accordingly, each lineage acquires its own unique array of molecular changes, which should make it increasingly different the longer it is in existence. On the other hand, by rooting an analysis in a particular taxon, one assumes that this taxon is totally primitive relative to the taxa whose sister taxon it is presumed to be. Yet the molecular assumption validates the use of overall similarity as the key to resolving phylogenetic relationships by contrasting it with the unique differences that earlier divergent lineages accumulated along their own and distinct evolutionary trajectories. Clearly, both assumptions cannot be correct at the same time. Either the earlier divergent taxa or lineages did not change but rather remained primitive (which is the logical extension of identifying a taxon as the out-group in which to root a computer analysis), or they did change by accumulating their own suites of molecular difference (the basis of the molecular assumption), in which case they are at least in some aspects derived (and uniquely so, for that matter, due to their distinctive molecular histories) and not primitive relative to the taxa being compared with them.

In the realm of morphological systematics, according to Hennigian or cladistic principles, overall similarity is not *de facto* a clue to evolutionary relatedness. Similarity must be sorted out into features that reflect a hierarchy of inheritance—primitive features from ancient ancestors and derived features from more recent ancestors.

Because the pattern of life is a hierarchy of nested sets of smaller and smaller clades, interpretation of primitiveness versus derivedness depends on the hierarchical level that one is investigating. Primitive features (those retained in descendants) do not elucidate the relationships of taxa sharing them. Only

derived features (those more recently emergent) can. Furthermore, one must understand that a derived feature at one level is a primitive retention at another level of the hierarchy. As Templeton suggested, theoretically at least, this approach should be applicable to molecular data. But to be cladistic, the comparison must embrace a wide range of taxa because this is the only way in which relative primitiveness and derivedness can be determined. It cannot be justified by *a priori* assumptions of directionality (i.e., the molecular assumption) or of relatedness or by comparison with a taxon that is defined from the beginning as primitive. In addition, one cannot assume that shared similarity translates directly into a theory of relatedness. Taxa may be similar not because they inherited changes that distinguished a recent common ancestor but rather because they share features that did not change from the ancestral condition.

Nevertheless, molecular studies are increasingly being identified as “cladistic.” One argument is that nucleotide bases—C, G, T, and A—represent alternative character states. This might seem logical but is incorrect because bases are characters. Alternative molecular character states would be better represented, for example, by different arrangements of “gene” sequences with regard to *cis*, *trans*, and interchromosomal elements; patterns of introns and exons and of methylation of transposons or other elements; or pathways of molecular communication. Molecular systematists also claim that their analyses are cladistic because “shared molecular similarity” is supposed to equate with “shared derived.” This, of course, reflects the molecular assumption, namely that recently diverged taxa share recently accumulated (and thus supposedly derived) molecular states. Thus, one identifies shared derived molecular states *a posteriori*, *after* one’s chosen algorithm clusters taxa on the basis of their being more or less similar and also typically after rooting one’s tree in a particular taxon. But this is not a cladistic analysis. The hypothesizing of primitive versus derived character states (themselves testable hypotheses) occurs *prior* to generating theories of relationship, and this is the only way in which the results of this can be testable.

Also deserving of comment is the assumption of continual molecular change that Zuckerkandl and Pauling used to explain their data: “over-all similarity *must* be an expression of evolutionary history” (emphasis added), with descendants “mutating away” from each other, becoming “gradually more different

from each other.” Molecular clocks and UAR, for example, are predicated on this notion. Nevertheless, this is not a demonstration but rather an extrapolation of how something might occur.

The contradiction is that although the molecular assumption also predicts that constant molecular change will occur during gametogenesis, the only physical source of molecular change is ultraviolet radiation, which produces a very low mutation rate of 10^{-8} to 10^{-9} that is random with regard to affecting somatic or sex cells and specific molecules. Thus, any apparent concordance between the reality of the physical world and the concept of a constantly changing molecular world is an illusion.

The notion of constant and accumulative mutation affecting sex cells (the only way in which molecular change can be transgenerational) also contradicts the tendency of cells to be homeostatic, for example, via heat shock proteins that maintain cell membrane physical states through lipid transport, eliminate reading errors that occur during transcription and translation, chaperone other proteins, and ensure proper folding of other proteins such as transcription factors. This makes sense because unabated molecular change would undermine the integrity of cell function and would more likely lead to death than to organismal change.

It may be widely believed, and even true at some level, that “genomes diverge as a function of time,” as Sean Carroll recently reiterated. But the fact that genomes differ (in whatever way in which difference, or similarity, is identified) does not inform how this difference arose. No doubt, some difference is due to the rare and random effects of ultraviolet radiation. Genomic difference may also be due to failed DNA repair or, as Britten and Kohne offered, saltatory events. Sibley and Ahlquist’s “law of large numbers” may have an intuitive appeal; organisms are closely related because they share “lots” of their genome. But as Marks pointed out, humans share approximately 25% of their genome with bananas. Essentially, there is nothing in the detection of genomic difference or similarity that demands the “molecular assumption” or a theory of evolutionary relatedness.

How might we think about “morphology” and “molecules”? Is there really an evolutionary gulf between the two?

A major area of inquiry in developmental biology is how cells acquire positional information with regard to entire structures (e.g., where limbs will

grow) and their components (e.g., limb segments). Morphological differences may be considered in light of differences in regional and overlapping domains of regulatory gene expression as well as in fields of molecular gradients (morphogenetic fields). As C. O. Lovejoy and colleagues hypothesized in 1999 with regard to the emergence of human pelvic shape,

If a particular PI [positional information] gradient were to span n cell diameters, and those cells defined the ultimate anteroposterior dimension of the presumptive ilium (superoinferior in the adult human), then a slight increase in the steepness of its slope would cause that signal to span fewer cells, “distorting” the presumptive anlagen and substantially altering downstream adult morphology.

In other words, although traditionally conceived as involving myriad steps, “the transformation of the common ancestral pelvis [in its entirety] into that of early hominids may have been as ‘simple’ as a slight modification of a gradient.” Thus, morphological novelty can arise via differences in gene expression and pathways of molecular communication and shifting domains of morphogenetic fields in conjunction with the physical and mechanical consequences of cellular organization—and it is at these levels of molecular interaction, not the accumulation of point mutations, that one should address questions of phylogenetic relatedness and also seek a connection between molecules and morphology.

One must realize that there is a difference between change at the genetic level and perceived phenotypic change. Common in the literature on the genetics of evolution is mistaken conflation of the two as constituting macromutation, the origin of species. Nevertheless, especially with increasing awareness from molecular biology that there are not “genes for” features, we must distinguish between what appears morphologically to have been the result of a macromutation (e.g., developing feathers instead of scales) and the underlying genetic–epigenetic interactive pathways.

As M.-C. King and A. C. Wilson alluded to in 1975, it is not through determining overall molecular or genomic similarity of organisms that we will understand their biology; rather, we will understand through delineating the development of their biology. This makes sense. If the inactivation or deletion of a transcriptional enhancer can shift sacral position caudally, or if expansion of a morphogenetic gradient

can fully transform a primitively narrow pelvic girdle with tall, thin ilial blades into a hominid's broad, deep, and squat structure, it is by studying these molecular events that we may profitably explore the molecular basis of morphology and consequently, through the analysis of both, the evolutionary relationships of complex organisms.

It is, then, appropriate to both question and expand our perceptions of what is or will be evolutionarily revealing at the molecular level. There has been a steady increase in the number of studies that demonstrate virtual molecular identity between taxa that are morphologically very different and then express astonishment at this apparent contradiction. As Carroll pointed out with regard to expectations of the human and chimpanzee genome projects, demonstrating molecular similarity is not equivalent to deciphering the pathways that make these hominoids so different in hard- and soft-tissue anatomy, physiology, reproductive biology, cognitive abilities, and behavior. Here, the “law of large numbers” fails to enlighten. Unlike in bacteria, in metazoans there is not a strict correspondence between a “gene” (a sequence of nucleotides bound by start and stop codons) and a “gene product” (a protein). In multicellular animals, RNA essentially directs the “show,” for example, in reading select bases and splicing specific introns as it composes different proteins from the same stretches of DNA. The surprise that the International Chimpanzee Chromosome 22 Consortium had on comparing human chromosome 21 with its apparent chimpanzee counterpart chromosome 22—finding that these hominoids differ by 83% in their amino acid sequences but that this significant difference derives from very similar DNA sequences—provides a lesson: It is time to go beyond mechanically comparing molecular sequences or entire genomes and fanning the flames of a “molecules versus morphology” debate in seeking insight into evolutionary relationships. In light of molecular and developmental biology, the former is naive and the latter is certainly artificial.

MORRIS, DESMOND (1928–)

Desmond Morris has been referred to as a Renaissance man. He is widely known in both scientific and artistic circles. He has been a prolific author of children's and adult books, nonfiction and fiction. He has made films and hosted television programs on animal behavior and other zoological topics. He has also been a successful surrealist painter for over 50 years.

Morris was born in the village of Purton, Wiltshire, England, in 1928. Even as a young child, he had a strong interest in natural history. Attending Birmingham University, he earned a BSc in zoology followed by a PhD in animal behavior from Oxford University. His thesis was on the reproductive behavior of the ten-spined stickleback.

After being awarded his doctorate, Morris moved to London to become the head of the TV and film unit at the London zoo. He simultaneously studied the artistic abilities of apes. He authored a number of natural history books and hosted a popular TV show, *Zootime*, for several years.

In 1967 Morris authored an international best-seller titled *The Naked Ape*. This work was quite controversial and made him infamous. In it, he used his zoological background to objectively study human behavior. He defines humans as simply another species in the ape family and relates complex human behavior to that of the lesser apes. While many scholars were incited by the content, and content that was not included, millions of copies of *The Naked Ape* were sold worldwide in two dozen languages. Morris left out detailed data and statistics, making his work comprehensible to the average reader. He did footnote his research and data for each chapter at the end of the book for those interested in the research supporting his commentary. After the success of *The Naked Ape*, he relocated to the island of Malta to paint and continue his writing.

Two more significant works quickly followed. In 1969, *The Human Zoo* continued the frank observations of *The Naked Ape* by scrutinizing the society that humans have created for themselves. He saw the neurotic behaviors exhibited by animals confined in zoos reflected in the humans living in crowded cities—"human zoos."

Intimate Behavior, published in 1971, looks at physical contact between human beings. He analyzed the roots of human intimacy from before birth throughout the life span; not only sexual intimacy, but social intimacy, object intimacy, self-intimacy, and substitutes for intimacy when it is lacking.

Morris has traveled extensively around the world making observations and gathering data for his research. He has coauthored several books with his wife, Ramona Morris. Galleries frequently exhibit his paintings. In addition to his art and animal behavior research, Morris has written reference books on dogs, cats, amulets and charms, horses, soccer, and more.

A lively intellect and engaging narrative style ensure a wide readership.

In the decades since his first noteworthy studies were produced, Morris has persisted in fascinating us with his observations of his fellow humans. He has continued to produce television and film documentaries, write prolifically for adults and children, conduct animal behavior research, and paint. His broad range of interests from the sciences to the arts does confer on him the title of a modern Renaissance man.

MULLER, FRIEDRICH MAX (1823–1900)

Friedrich Max Muller was a prominent 19th-century scholar whose voluminous writings popularized the study of Indo-European languages, comparative linguistics, mythology, and Eastern religious thought. He was notable for his varied interests and broad comparative theories and was the author and/or editor of more than 100 books. Like other scholars of his day, including Edward B. Tylor and Sir James Frazer, Muller derived his theories from texts rather than from personal experiences. Biographer Nirad C. Chaudhuri praised Muller for having brought a sympathetic portrayal of Eastern cultures and religions to a European audience. But as Laurens R. van den Bosch emphasized, Muller never actually visited India. Perhaps Muller's best-known scholarly achievement is his editorship of *The Sacred Books of the East*, which was published in 50 volumes between 1879 and 1894. This collection constitutes an important compendium of both Hindu and Buddhist thought. In addition, Muller was responsible for introducing European

audiences to a number of previously unknown Japanese Buddhist scriptures.

Born in Dessau, Germany, Muller was the son of the Romantic poet Wilhelm Muller. The young Muller evidenced an early interest in comparative language studies and studied philosophy, linguistics, and languages at the universities of Leipzig, Berlin, and Paris. Muller moved to England in 1848, became a member of Christ Church in Oxford, and remained at Oxford University for the rest of his life. At Oxford, Muller first taught modern languages. After being denied a professorship in Sanskrit in 1860, Muller's persistence and productivity were rewarded by his appointment as professor of comparative philology in 1868 (a professorship that was established especially for him). Although he was German born, nearly all of Muller's major publications are in English.

Muller is best known to contemporary anthropologists for his debate with Tylor, the founder of British social anthropology, concerning the origin of religion. This debate is still covered in most introductory anthropology textbooks. To summarize this debate, Tylor thought that the origin of religion is psychological experiences (especially dreams), whereas Muller opined that religion began with human perceptions of natural phenomena. Muller contended that at the root of all religions is the experience of the infinite provoked by nature, especially the power of the sun. He also postulated that most Indo-European gods were originally the names of natural phenomena that became falsely deified. Thus, as Muller provocatively asserted, religion is best understood as a "disease" of language. His actual theory, as presented in *Contributions to the Science of Mythology* (1897), is much more tentative and nuanced. He was not so much concerned with so-called diseases of language as with the expansive power of metaphor.

Muller's essays on mythology are among his most accessible writings. It was his explorations of mythology that led him to delve further into the study of comparative religions. As early as 1849, he had seen evidence of nature worship in Indo-European mythology, beginning with the gods of *Rig Veda*, who were portrayed as active forces of nature and only partly personified as imagined supernatural persons. According to Muller, myths transform concepts into beings and stories, and the gods (whose beginnings were words constructed to express abstract ideas) were mistakenly transformed into imagined personalities. Muller's theories concerning the significance

of metaphor anticipated the theories of 20th-century anthropologists such as James W. Fernandez and Claude Lévi-Strauss, and his speculations on Indo-European languages also inspired the work of Georges Dumézil.

Muller's scholarly legacy is mixed. He cultivated an engaging persona, hobnobbed with the elites of his day, and occupied a prominent place in Victorian intellectual circles. By all accounts, most of his public lectures were well received. As Roger O'Toole pointed out, during Muller's lifetime, his reputation rivaled that of Tylor, Frazer, and Robertson Smith, but today it is marked by indifference. O'Toole cited Émile Durkheim's critique of naturalism as one possible reason for the neglect of Muller's ideas. O'Toole also faulted Muller for his excesses and sweeping generalizations; nevertheless, he contended that Muller deserves recognition as a founder of the scientific study of religion. Muller himself had coined the term "science of religion" (*Religionwissenschaft*) in 1873, but his notion of science differed considerably from that of contemporary anthropologists. First, he did not embrace participant observation. Muller seldom looked beyond texts. Second, his biases were apparent. Muller was not an advocate of objectivity in the study of world religions and adamantly insisted that the comparative study of world religions would ultimately lead to a greater appreciation of Christianity.

As a comparative linguist, Muller's contributions were again mixed. To his credit, he advocated a modern contextual approach to the study of language and was among the first to suggest that the study of the language should be related to the study of the culture in which it had been used. He was also among the first to tie the development of languages to the study of belief systems, a theme developed in the writings of Benjamin Lee Whorf. But he has been widely criticized for assuming that religions are like languages that can be classified into "families." By and large, his translations of Hindu and Buddhist sacred texts are competent but have been largely superseded.

Finally, Muller's work contributed to a growing interest in Aryan culture that focused on Indo-European (Aryan) traditions as opposed to Judeo-Christian (Near Eastern) traditions. But this new focus had unintended consequences, and some of Muller's findings about the Aryan tradition began to be expressed in terms of racist ideologies. Muller had hoped, to the contrary, that the discovery of a

common Indian and European ancestry would serve as a powerful argument against racism.

FRIEDRICH MAX MULLER

The son of the poet Wilhelm Muller, German-born Friedrich Max Muller was an influential philologist and Orientalist. Muller is known for advancing philology and mythology as well as for his important works on Indian religion and philosophy. The growth of the study of various topics, including linguistics, mythology, and religion, is at least partially attributed to Muller. Although Muller was famous on an international basis in his day, his fame has decreased to the point that he is now known primarily by some scholars within the disciplines in which he was most influential.

One of Muller's important theories was the belief that mythology grows out of descriptions and understandings of natural processes. Muller was very interested in comparative religion and spent a

great deal of time studying Indian belief systems. One of his goals was to trace the history of Aryan people to find their common ancestry. This goal was an outgrowth of his belief (and that of other German Romanticists at the time) that the Orient was the origin of spirituality. The goal of discovering and documenting the history of the Aryan race was a driving force in Muller's career. Muller believed in learning about and understanding cultural and religious diversity, which was a very controversial notion during his time.

Muller was trained in Sanskrit at the University of Leipzig in Germany for both his undergraduate degree (1841) and his Ph.D. (1843). Muller continued his studies of philology and Sanskrit in Berlin. In 1845, he went to live in Paris and earned a living copying Sanskrit manuscripts. In 1846, the East India Company hired Muller to translate the *Rig Veda*, one of the primary texts of Hinduism. The result was a six-volume edition. The publication of the *Rig Veda* in 1848 catapulted Muller to fame, and he was offered a position at Oxford University. In 1854, he was hired as Deputy Taylorian Professor of Modern European Languages. Two years later, Muller became the curator of the Bodleian Library at the Oxford. Muller became a professor of comparative philology in 1868, and he became a privy councillor in 1896. Muller left his professorship in 1875, and from then until his death he dedicated his time to editing and translating portions of the 50-volume *Sacred Books of the East*. Muller authored and edited numerous books and essays. In addition, he translated many important religious texts and other works, including Immanuel Kant's *Critique of Pure Reason* (1881).

MULTICULTURALISM

Culture cannot be defined simply by our ethnic background. It is also family, religion, profession, interests, gender, child-rearing practices, educational background, where we live, the food we eat, our individual uniqueness, sexual lifestyles, and more. Even though we are better understood by someone who considers

our ethnic background, our own cultural definition is much broader than just an ethnic label.

Social Foundations of Multicultural Education

By formulating the scientific concept of culture and destroying the myth of race as a determinant of behavior, cultural anthropologists during the 1920s began to lay the intellectual foundations for multicultural/global education. Franz Boas, Ruth Benedict, Margaret Mead, and their colleagues provided a scientific basis for dealing with the crucial dilemma of the world today: How can people of different appearances, mutually unintelligible languages, and dissimilar ways of life get along together peaceably? This understanding of ourselves as a species capable of creating and carrying culture opened the way for thinking and believing more inclusively about the world. But it was not until the 1960s and 1970s that the image of a multicultural/global perspective burst on our consciousness. Visionary thinkers, best-selling books, and unexpected events sharpened and expanded our understanding.

In 1962, Rachel Carson astonished the public by describing the harmful consequences of the use of pesticides. In 1964, Marshall McLuhan described a "global village" with its people linked through communications technology. In 1964, Pierre Teilhard de Chardin wrote of the convergence of human aspirations and history into the noosphere, a progressive unification of humankind and intensification of our collective consciousness. In 1965 and 1969, Barbara Ward and R. Buckminster Fuller, respectively, conceived the metaphor of Spaceship Earth as a closed life support system with its inhabitants accelerating through time and space depending on each other for survival. In 1968, Paul Ehrlich called our attention to the stunning exponential growth rate of world population and impending ecological catastrophe. In 1970, Alvin Toffler warned of impending future shock. In 1972, Barbara Ward and Rene Dubos coined the now familiar notion of "thinking globally, acting locally." In 1972, the Club of Rome ignited a global controversy regarding the rapid depletion of our nonrenewable resources. And in 1974, the biologist Lewis Thomas portrayed the earth as a single living cell. Critical events on a national/global scale played an important role in raising our consciousness.

The challenge of multicultural/global education is, and will continue to be, the acceptance, respect, and

love that can be learned at young ages, as can bigotry, racism, and hatred. Robert Haveman and Barbara Wolfe argued that children's life success is determined by three primary factors: a social or government investment in their lives, a parental investment, and the choices that the children make over time. These authors highlighted that, in addition to parental influence, social institutions such as schools play a significant role in children's lives, so that the importance of good schools and teachers is without question extremely important.

Demographic Characteristics

James Banks estimated that the ethnic texture of the United States is changing substantially. The U.S. Census projects that ethnic minorities, including African Americans, American Indians and Alaska Natives, Asians and Pacific Islanders, and persons of Hispanic origin, would make up 29.4% of the U.S. population by the year 2000. At the time, American classrooms were experiencing the largest influx of immigrant students since the turn of the 20th century.

Understanding the demographics of the American nation is very important to multicultural education as it attempts to assimilate individual students into the dominant field and practices of the classroom. The focus is on the fostering of positive affective relationships among students of different backgrounds and personal characteristics in the school so that each student has a strong self-concept and can work in harmony with the group.

This approach to education promotes social equality and cultural pluralism that can be later transferred to the workplace. The third millennium promises to be as challenging as the second one was. Educators must build on students' learning styles, adapt instruction to the existing skills of students in the classroom, and involve students in thinking through and analyzing the life situations of different people. In managing cultural diversity, the first thing that we must understand is the ways in which people differ from each other. These ways are significant and numerous. Culturally, we vary in gender, age, ethnicity, race, sexual orientation, educational background, religion, physical/mental ability, military/veteran status, lifestyle, immigrant status, and language facility. Functionally, we vary in how we think, learn, process information, respond to authority, show respect, and reach agreements. Historically, culturally, and traditionally, we also vary in family makeup, perspective,

political outlook, and intergroup relationships. When groups are made up of people with many backgrounds, cultures, and lifestyles in a school or workplace setting, promoting teamwork and smooth interactions can be quite a challenge. Finding new ways of working together will require teaching and thinking about people's differences so as not to divide, separate, or exclude but rather to take advantage of those differences. We need to create environments that welcome and encourage the benefits of diversity.

The gap between our own experiences and personal identities and those of the students or workers may be small or may be tremendous. But there is a gap, and it will continue to grow as the student/workplace population becomes more diverse. Thus, the racial, cultural, ethnic, and gender differences at work today can cause trouble if they are not handled sensitively.

The new aspect about what is variably called "managing cultural diversity" and "multiculturalism" is the quantity and variety of differences in the schools and in the workforce. Educators, supervisors, and colleagues should be careful to interpret cultural behaviors correctly and not take offense where none is intended.

In the United States today, the traditional hierarchical, white male-dominated, large corporate environment is no longer the norm. In 2002, women constituted nearly two thirds of all new entrants into the workforce. One out of four people is African American, Hispanic, or Asian American. Immigrants make up the largest share of the U.S. population increase. There are more people over 65 years of age than there are teenagers. At least 10% of the population is gay or lesbian.

Diversity, Business, and Teaching

By learning and understanding the new perspectives brought by a wider range of a diverse population, we can provide better services to the business clients and our schoolchildren. For example, Carlos Diaz, professor of multicultural education at Florida Atlantic University, believes that as a general rule the higher the average socioeconomic status of a school's student population, the more favorably it will compare with the following criteria. The average social class of a school will affect the proportion of high-status (advanced placement) courses available to students, the proportion of the faculty members holding temporary or emergency teaching credentials, the

average level of per-pupil funding the school has available (which affects the books, materials, and field trips available to students), student expectations of success in the college preparatory courses, and teacher expectations of high student achievement.

Common sense and the education literature tell us that students have different learning styles and that learning the new perspectives brought by a wider range of employees, educators, and business people can provide better services to students and clients. New perspectives will enhance our problem-solving skills and allow us to make better and more inclusive decisions. Business people and educators can learn to ask better questions initially, to identify new areas of opportunity and increase customer satisfaction as well as enable students to succeed, and/or to adapt to the requirements of the traditional classroom.

Learning style is a complex idea and involves how people perceive, process, store, and retrieve information. In a learning situation in the workplace or at school, to what cues does an individual attend? How does the individual connect cues? What strategies does the individual use to make sense of new information or ideas? With what "old information" in the individual's head is the new information connected and stored? Everyone develops ways of approaching these information-processing tasks, but not everyone develops in the same ways. One way in which to view learning is as information processing. Howard Gardner's idea of multiple intelligences is another way. According to Gardner, there are at least seven different kinds of intelligence, and everyone has a profile of strengths and weaknesses. These include linguistic intelligence and logical-mathematical intelligence (which schools and businesses focus on most heavily), musical intelligence, interpersonal intelligence, intrapersonal intelligence, spatial intelligence, and bodily-kinesthetic intelligence.

Learning styles overlap somewhat with cultural background and gender. It is important for the workplace and all educational settings to understand that not all members of a cultural or gender group learn in the same way; patterns exist concerning how members of different groups tend to approach tasks. These patterns develop due to factors such as child-rearing practices and the roles that children are expected to occupy as adults. Rather than generalizing about students and workers, it would be more useful to investigate and learn the learning style preferences of the students and people in the workplace.

Core Values in Multiculturalism

Multiculturalism has ideological overtones based exclusively on democratic ideals that are lacking in less controversial educational content areas such as mathematics, reading, and computer science.

Four core values provide the basis for an educational and workplace model that will acknowledge that multiculturalism is not a fad but rather a fact of life in the United States today and tomorrow: acceptance and appreciation of cultural diversity, respect for human dignity and universal human rights, responsibility to the world community, and reverence for the earth.

These core values are rooted in democratic theory and Native American philosophy. Together, they illustrate the strong ethical foundations of multiculturalism. In the workplace, the trend in management is away from autocracy and toward consensus. More corporations are shifting from a hierarchical structure to individual contributors and teams.

This shift requires new skills of communication, negotiation, collaboration, and team building. Leaders in the field of education and business must orchestrate teams composed of diverse individuals, and gaining full cooperation from everyone on the team is critical to performance. Businesses will receive many benefits by recognizing and encouraging workforce diversity. Among the many benefits, consider the economic impact of tapping into the tremendous purchasing power of older Americans, African Americans, and Hispanic Americans, among others. As another example, consider the impact of reducing costs by reducing employee turnover given that highly trained workers will stay with organizations that are responsive to their needs, that is, if businesses understand and implement multiculturalism; corporations know that retraining is expensive, and high employee turnover reduces morale and productivity.

Businesses can reap the benefits of productivity, creativity, and innovation from all employees by promoting new perspectives and, therefore, enhancing problem solving. An inclusive environment both at school and in the workplace builds respect, ownership, and loyalty. The process of becoming multicultural is one whereby a person develops competencies in multiple ways of perceiving, evaluating, believing, and doing.

The focus of multiculturalism is on understanding and learning to negotiate cultural diversity among

nations, within a single nation, and among individuals. For example, in their book *Communicating With Strangers*, William Gudykunst and Young Kim described the multicultural person as one who has achieved an advanced level in the process of becoming intercultural and whose cognitive, affective, and behavioral characteristics are not limited but rather are open to growth beyond the psychological parameters of any one culture. The intercultural person possesses an intellectual and emotional commitment to the fundamental unity of all humans and, and at the same time, accepts and appreciates the differences that lie between people of different cultures.

According to Gudykunst and Kim, intercultural people have encountered experiences that challenge their own cultural assumptions and that provide insight into how their view of the world has been shaped by their culture, can serve as facilitators and catalysts for contacts between cultures, come to terms with the roots of their own ethnocentrism and achieve an objectivity in viewing other cultures, develop a Third World perspective that enables them to interpret and evaluate intercultural encounters more accurately and thus to act as a communication link between two cultures, and show cultural empathy and participate imaginatively in others' worldviews.

Why Is Multicultural Understanding Essential?

Education

Demand for the reform of schooling in the United States was a continuing theme throughout the 20th century. The educational reform movement gained new momentum during the mid-1980s, beginning with the Reagan administration's report titled *A Nation at Risk*. Nearly a dozen additional major reports on U.S. schools appeared in 1983 alone. The common thread throughout these reports was the demand for a national commitment to true excellence in education.

What many of these reports did not acknowledge, however, is that educational excellence in our schools cannot be achieved without educational equity. Equity in education means equal opportunities for all students to develop to their fullest potential. Evidence of inequity in education exists in the nation's school dropout rates, which are disproportionately high among African American, American Indian, and Hispanic youths as well as among the poor. In many

schools across the nation, racial and language minority students are overrepresented in special education and experience disproportionately high rates of suspension and exclusion. The majority of African American and Latino students attend schools with large concentrations of economically disadvantaged and/or lower achieving students due to outdated texts, poor facilities, and/or inadequately prepared teachers.

There is a lot of rhetoric in education and the workplace about the human potential and the need for equality of opportunity. Multiculturalism moves beyond the rhetoric and recognizes that the potential for brilliance is sprinkled evenly across all ethnic groups. When social conditions and school practices hinder the development of this brilliance among students outside the predominant culture, as is the case within the society, the waste of human potential affects everyone. The cumulative loss of talented scientists, artists, writers, doctors, teachers, spiritual leaders, and financial and business experts is staggering.

Multiculturalism also contributes to excellence in another important way in that it builds knowledge about various ethnic groups and national perspectives into the curriculum. The traditional curriculum is filled with inaccuracies and omissions concerning the contributions and life conditions of major ethnic groups within our society and for nations across the planet. Obviously, the attainment of any degree of excellence is stunted by curriculum content that is untrue or incomplete. Given that we live in an interdependent world that is shrinking rapidly, and in light of the events of September 11, 2001, ignorance of global issues and national perspectives is foolish and even dangerous.

The Business World

Local, state, and federal laws prohibit discrimination based on race, gender, religion, and/or other factors. The laws regarding discrimination require a company found guilty to pay all damages, including all attorney fees and court costs. Plaintiffs are awarded millions of dollars every year.

Corporations have begun to ask the difficult questions that are required to orchestrate teams composed of diverse individuals, and gaining full cooperation from everyone on the team is critical to performance.

The corporation must be concerned about the welfare of its working force. It must promote diversity by challenging people to spend time together during lunch, to work on different projects equally with

people from different races and ethnic backgrounds, to provide supplemental training equally to all employees, to promote employees based solely on their qualifications, and to ensure that no group of employees are hired only for certain jobs. Finally, in an effort to recruit and keep good employees of all races and ethnicities and of both genders, Fortune 500 companies have begun to address diversity issues in the workplace.

What Can the Education and Business Worlds Do to Promote Diversity?

As both educators and business executives, we can read articles, books, and journals. We can keep our ears and eyes open and can attend special events, programs, and seminars. We can learn about some of the diversity issues faced by others. If we do not understand something about a culture different from our own, we can ask. What do our colleagues and associates think about our school/organization and its willingness to address multicultural issues? What have they experienced, both positively and negatively, about diversity? Keep in mind that a broad definition of diversity includes all types of human differences—age, gender, ethnicity, positions in the organization, education level, immigrant status, seniority, language facility, and sexual orientation, to name a few.

What do our school's or company's formal statements, such as the vision, mission, goals, and objectives, say about how the school or company conducts its business? Are any direct references made to multiculturalism? If so, it should be easier to build support and find funding in education and also should be easier for a business that is formally committed to diversity. Everyone in school and in the workplace should be a catalyst, a researcher, an advocate, a problem solver, a facilitator, an influencer, a supporter, and a strategic thinker so as to promote and comply with the multicultural vision statement of their institution.

The Social Relations of Class, Race, Gender, and Crime Control: Inequalities of Crime, Culture, and Production

Examining class, race, and gender in relation to law, order, and crime control provides an appreciation not only of multiculturalism but also of the unique histories of the individual social groupings

and interrelated axes of privilege and inequality. In multicultural education, it has been shown, in terms of the history of the social realities of justice in America, that the experiences of diverse groups of people in society have contributed to the shaping of conceptions of criminals and victims. These experiences have helped to shape not only the way in which racial and ethnic majorities have come to regard specific legitimate and illegitimate behaviors but also the patterned ways in which they have (or lack) access to institutional power and privileges.

In the understanding of multiculturalism, the study of class, race, gender, and crime reveals several broad themes about how bias undergirds the construction of what will and will not be seen as criminal. This bias also shapes the construction of individual experience and identity, which varies according to one's socioeconomic position in society. More specifically, there are at least four related assumptions regarding the understanding of the social relations of class, race, gender, and crime control. These categories of social difference all share similarities of justice, especially as they relate to power resources and to the allocation and distribution of rewards and punishments in society. The systems of privilege and inequality derived from the social statuses of class, race, and gender are overlapping and have accumulating effects on the type of crime control that various groups of people encounter. There are connections among these systems of difference, inequality, and privilege in that each helps to reproduce the social divisions of hierarchy and stratification that dynamically affect people's life experiences inside and outside the criminal justice system. And according to relationships of power, status, and authority, systems of crime control socially construct selectively enforced and differentially applied norms to social groups.

The process of changing organizational cultures, as well as social relations of class, race, and gender, is a long-term and difficult process. There is inevitable resistance to alterations of fundamental ways of doing business that have changed little in half a century in many schools and workplace environments.

It is clear that excellence in managing diverse groups will require changes in culture in schools and workplaces. To create this change, we must understand culture with the objective of creating a climate in which members of all identity groups excel. We must understand pluralism with the objectives of creating a two-way socialization process and ensuring

influence of minority culture perspectives on core educational and business organization norms and values.

We must understand structural integration with the objective that no correlation should exist between culture and group identity in the school or workplace in the form of job status. We must understand integration in informal networks with the objective of eliminating barriers to entry and participation. We must understand institutional bias with the objective of eliminating bias ingrained in management systems in both school and workplace environments. Finally, we must understand intergroup conflict with the objectives of minimizing interpersonal conflict based on group identity, minimizing backlash by dominant group members, and promoting intergroup understanding.

Multiculturalism is not an easy concept to understand. However, it provides an opportunity for all children to see themselves in the literature. It fosters development and positive self-esteem at school and in the workplace. It strengthens the significance of personal heritage. It helps to raise personal aspirations. It provides for everyone to learn about people all over the world. It recognizes and values the contributions of all people. It helps to build a global community. It blends easily into themes of study found in schools. Most important, it prepares us for the future.

If we work together, learn from each other, and share something of ourselves, we can develop deeper understandings and a tremendous appreciation for our differences, as well as our similarities, at both the local and global levels. We can cultivate our differences, or we can celebrate them.

MUMMIES AND MUMMIFICATION

The term *mummy* describes the corpse of an organism where decay is arrested for a considerable period of time and a semblance of life-like appearance is preserved. Some natural environments can mummify animal and human bodies spontaneously, thereby preserving them over great periods of time. Mummification practices by humans occur worldwide and may represent significant processes designed to preserve a body for important cultural, religious, or political purposes. The exceptional preservation of soft tissues can provide detailed information about ancient environments, cultures, and the evolution of disease not always achievable by traditional interpretations of archaeological assemblages.

Mummification involves the transformation of a once living body or tissue into a state of arrested decay by regulating or denying the water, temperature, or biochemicals necessary for complete decomposition. In the context of the term *mummy*, the process of mummification also infers the preservation of enough soft tissue to resemble its living morphology for a prolonged postmortem interval. Mummification may be classified broadly into two categories: anthropogenic (where humans promote the mummification process) and spontaneous (where natural processes occur to cause the preservation without human intervention).

The origins of the word *mummy* lie in the rocks of 1st-century AD Persia, where deposits of natural bitumen were called *múmiyá* after an Arabic word for “wax.” The black tarry substance became popular for medicinal purposes, and by the 13th century the natural deposits could not satisfy burgeoning European demand. So, the black resins found in mummified Egyptian bodies were substituted; thus, the term *múmiyá* was transferred to the resin and later to the ancient human remains. Mummies still

found themselves in the service of humans, but in a purpose far removed from that of their original internment thousands of years earlier.

The earliest known example of anthropogenic mummification is from the Chinchorros culture of northern Chile dated at 7,800 years of age. Since at least that time, humans have practiced mummification on every inhabited continent of the earth. Although mummification is widespread historically and geographically, it remains a highly anomalous human mortuary practice compared with the more common methods of burial and cremation for reasons of health and economy. This fact, combined with recognition that the practice of mummification was usually an expensive undertaking in terms of energy, time, and materials, surely indicates the power of motivations for its use by different cultures. Perhaps the source of public wonder and scientific rigor toward anthropogenic mummies is the question of purpose they inherently generate.

Reasons for Mummies

Many cultures share the belief that a deceased person’s vital force or spirit remains with or in the vicinity of the person’s body for some period after death. Most mortuary practices reflect a desire to pacify or hasten the departure of such spirits, but some others use the mummification process to exploit and regulate this force. For example, in Aleutian Islands culture, the bodies of dead leaders would be mummified and stored in caves or homes so that the living could continue to consult the remains for advice or prophecies, and some parts of the bodies would be carried on hunting trips because the entrapped vital force was expected to enhance success.

A motivation for anthropogenic mummification that has persisted even from historical times is that of war trophies such as “headhunting,” where boiling and drying the heads of human enemies causes them to shrink and preserve so that they may be carried easily and displayed over time, instilling status to the wearer and other tribal members. Other values may include magical properties for rituals and security from the deterrent effect to hostile neighbors. It is documented that from the time of early Inca expansion, the Sausas of Peru sometimes skinned their military captives, filling the skin with ashes and sewing it up to erect “skin mummies” in their temples as war trophies.

Mummification as used by Inca, Egyptian, and Roman cultures may be understood from the motivation of political power. Monarchs would install themselves as spiritual deities to increase their authority and power, but such claims of royal divinity then required a series of rituals to instill and support such belief in the public's mind. Perpetuating the remains of a dead king via mummification made the associated divine body available to assist and support the structures of theocracy, linking the currently reigning monarch with the immortal gods by the deceased divine king for the perceived benefit of the people. Continuing display of the mummified remains in overtly visible tombs, such as the Egyptian pyramids, acted to remind the population of the deity status and authority of the king's office. Later there evolved a more personal motive for mummification after the erosion of royal power made the expensive process socially accessible. There arose a personal status from being able to afford mummification in addition to any other religious belief of extension to the afterlife.

Anthropogenic mummification practices have not been used exclusively on human bodies, and those used on other bodies may be preserved by methods similar to those employed for humans. Massive numbers of different animals were mummified by Egyptian guilds exclusively for sale to the public for use in totemic rituals, and pets were also mummified and buried in tombs with their owners. In many other cultures, the practice of sacrificing and mummifying animals may be considerably different in intent from that of mummifying humans, for example, to attract the animal's spirits for assistance with hunting or to appease the spirit of slaughtered prey.

Mechanisms of Mummification

Immediately after death of a living body, highly regulated enzymes in cellular tissue become deprived of vital regulatory controls and begin to autodigest and liquefy the surrounding cells. This process of self-destruction, called autolysis, is the first of a series that acts to break down once living tissue into constituent molecules and return them via soil, water, and atmosphere to the biochemical pool from which all life originates. Mummification can interrupt this cycle by regulating or stopping different parts of the decomposition process.

Because postmortem decay is an enzymatic process and enzymes require an aqueous medium, drying of

body tissues is an effective inhibitor of decay and is the most common form of both spontaneous and anthropogenic mummification. This happens naturally in hot dry environments such as are found today in the Atacama region of northern Chile, where one can witness animal carcasses, locally reported to be hundreds of years old, so well preserved as to appear only weeks dead. Desiccation may also take place in cold dry environments by sublimation ("freeze-drying"), as evidenced by spontaneously mummified seals exposed in ice-free areas of Antarctica that are radiocarbon dated to be 2000 years old. Because such hyperarid environmental conditions have been intermittently active on the earth for hundreds of millions of years, prehistoric animal mummies have occurred and may be fossilized in geologically rare events. Several dinosaur specimens with abundant fossilized skin and other soft tissues suggest that conditions favorable for spontaneous mummification were active during the Cretaceous period.

Anthropogenic mummification harnesses natural processes to promote desiccation and effect preservation. Evisceration was commonly employed to remove rapidly liquefying organs and promote airflow within the abdomen to hasten desiccation. The drying of a corpse was helped by positioning it in a well-ventilated area, such as the mouth of a cave or on a raised platform, but in wetter climates the process could be forced by exposing the body to fire. A corpse could also be stuffed with desiccants such as cloth and grass, or in areas with suitable ores it could be enveloped in sodium carbonates for a period of time to effect water transfer from the tissues. After desiccation, some cultures wrapped bodies in cloth soaked with botanical resins or sealed them in containers to shelter the remains from subsequent rehydration. There are some (mostly anecdotal) historic accounts of mummification by immersion in honey, including the remains of Alexander the Great and the Agesipolis king of Sparta in Libya, but modern experiments have shown that although honey can desiccate small samples of tissue via an osmotic effect, this has not yet been proven for use on whole bodies.

A different but spectacularly effective type of mummification occurs when a dead body is enclosed within a peat bog containing sphagnum moss. Compounds in the peat act to make calcium unavailable to enzymes and destructive bacteria and thereby halting their destruction of soft tissue, while the same process of calcium removal causes skeletal elements to dissolve away. These so-called “bog people” have the finest details of soft tissue preserved and are some

of the best examples of humans dating back to the Neolithic.

Decomposition is also affected when temperature is lowered to levels that essentially suspend enzyme action, and this may halt decay for very long periods. Spontaneously mummified Siberian mammoths recovered from glacial ice show very good gross morphology after 44,000 years, and the 5,000-year-old corpse of a man buried by a glacier contained delicate features such as eyeball tissue and tattoos of the skin. Ancient Inca people took advantage of low temperatures and the sublimating environment found on high Andean mountain peaks to mummify bodies, a technique reflected in the modern mum-

mification practice where liquid nitrogen is used to snap-freeze bodies in the effort toward long-term preservation.

Contemporary mummification is also achieved by embalming, which in modern practice predominantly involves intraarterial injection of chemicals such as formaldehyde to temporarily preserve a body until family members may view it before burial or cremation. The remains of some historical figures, such as Vladimir Lenin, Eva Peron, and Mao Tse Tung, have been preserved in such ways for political or other purposes. The use of arsenic in embalming fluid formulas was once popular and effective, but eventually it was discarded due to its toxicity and potential to confound the postmortem identification of arsenic poisoning in murder victims.

Abuse and Use

Throughout antiquity, looters have targeted mummies to recover precious adornments and to trade whole mummies to collectors. These practices denigrate the integrity of specimens, but modern humans have at times devised even more destructive fates. Mummies have suffered from being “harvested” and pulled apart to recover their linen wrappings for paper manufacture, or the remains have been ground down to provide substances for medicinal purposes. Even animal mummies have not been exempt; for example, 200,000 mummified cats recovered from an Egyptian necropolis site were transported to England and processed as fertilizer.

Such loss should be lamented. The exceptional preservation of soft tissues in mummies can provide detailed information about ancient cultures and historical events not always achievable by traditional interpretations of archaeological assemblages. The discovery of fish tapeworm ova within gut contents of South America's Chinchorro mummies not only confirmed archaeological suggestions of marine subsistence, but also confirmed that the Chinchorro people habitually ingested uncooked fish. The mummified remains of some polar explorers have allowed post-mortem autopsies decades after the events, in some cases determining an unlikely cause of death such as lead poisoning or parasites developed by ingesting uncooked polar bear meat. Sometimes the objects and chemicals associated with a mummified body may provide information such as the identification of embalming agents and adornments that may indicate their provenance and extent of trade between cultures of the region at the time. Mummies are also being used increasingly in the area of health, where their retention of pathologies in soft tissue is being used to observe the rate of change in disease with time. Tracking the evolutionary path of disease between ancient people and modern humans may provide clues to control current or future afflictions.

MUNGO LADY/MAN

Lake Mungo is 1 of a series of 17 dry lakebeds in the Willandra Lakes World Heritage Area of Mungo National Park in New South Wales, Australia. Today the area is extremely arid, and the lakebeds rarely retain water except at the peak of a flood, but from 40,000 to 20,000 years ago, this area contained an enormous system of freshwater lakes connected by creeks. This ecological system was rich in plant and animal life, and it supported thriving Aboriginal communities. These communities from the distant past are the source of some of the most valuable archaeological sites in Australia, including the burials of Mungo Lady and Mungo Man.

In 1969, Jim Bower of the University of Melbourne found most of a skeleton buried in a hearth near the shore of Lake Mungo. The bones belonged to a woman who had died at approximately 19 years of age. Mungo Woman had been cremated, and the charred bones that remained had been smashed to pieces. The remains had been gathered and buried in a small cylindrical grave. Scholars dated the burial to 40,000 years ago, making Mungo Lady the oldest evidence of cremation in the world.

Five years after Mungo Lady was found, the bones of a male—later dubbed Mungo Man—were discovered nearby. Mungo Man was approximately 50 years old when he died. Before being interred in a shallow grave, he had been laid out with his hands clasped and his knees flexed. Red ochre had been painted all over his body, staining the burial sand pink. Mungo Man's burial was also dated to approximately 40,000 years ago, making Mungo Man the oldest evidence of a ceremonial burial.

Various methods were used to test sand from the actual burials of both Mungo Lady and Mungo Man to date the remains as accurately as possible. During recent years, dates as varied as 26,000 to 50,000 years old have been applied to these burials. The discrepancy was the result of testing sand from the soil layer where the remains were found but not from the burials themselves. Stone tools found in sites at Lake Mungo and other lakes in the region have also been dated to nearly 50,000 years ago, supporting theories that humans occupied many areas of Australia at that time.

Life at Lake Mungo, especially from 40,000 to 30,000 years ago, was ideal for Aboriginal tribes.

There was abundant fresh water, and animals were plentiful. Bones of many animal species have been found, including the butchered remains of Tasmanian tigers, giant kangaroos, and *zygomaturus*, all of which are now extinct. Scientists have also found mussel shells and fish bones. Tools for grinding flour have been located. Human bones that have been found show very few signs of malnutrition, and fractured bones appear to have healed well. All evidence points to a well-fed, healthy group of people.

Today these former lakes are in a semiarid zone on the eastern edge of the continental dunefield. Rainfall is low and erratic. The dry lakebeds have sparse vegetation suited to desert climates. The eastern sides of the lakebeds have lunettes, which are crescent-shaped dunes formed by the predominantly westerly winds. Human burials, middens (garbage heaps), hearths, earth ovens, and stone quarries all have been found on or near these lunettes. More than 300 sites have now been recorded from the Willandra Lakes region, making the whole region valuable to archaeologists. Mungo Lady and Mungo Man especially have changed the way in which scientists view Aboriginal history.

MURDOCK, GEORGE PETER (1897–1985)

George Peter Murdock was an American anthropologist, with strong roots in Yale University sociology, whose major contribution was the testing of propositions with ethnographic data drawn from large samples of societies representing all levels of sociopolitical complexity. He achieved this through a series of cross-cultural studies that focused on various aspects

of social organization, including descent systems and kinship terminology. This work reached its culmination in *Social Structure* (1949), a study that is probably the most outstanding book in anthropology of the 20th century. This book, which is still being cited today, established Murdock as the leading student of social organization in America. During the 1950s and 1960s, social organization research dominated both American and British anthropology.

Through a series of studies that spanned nearly his entire career, Murdock developed the database that made modern cross-cultural research possible. William G. Sumner of Yale during the late 19th century compiled files of ethnographic information on societies that he used in his comparative studies. (Sumner's files are housed at the Human Relations Area Files [HRAF] headquarters in New Haven, Connecticut.) Murdock approached the data in the same manner when he wrote *Our Primitive Contemporaries* (1934), a textbook that provided ethnographic accounts of 18 societies arranged from the simplest to the most complex. By 1937, Murdock had founded the Cross-Cultural Survey, a compilation of published ethnographic materials on 90 cultures. To produce comparability of cultures, an *Outline of Cultural Materials* (1938) was developed to sort the passages that had been directly copied from ethnographies. Ten years later, Murdock invited other universities to join a consortium, leading to the founding of the HRAF in 1949. To assist in the development of the database, a listing of all known cultures, *The Outline of World Cultures* (1954), was published. The next major step was publication of the codes of data that Murdock had used in his cross-cultural studies. His first endeavor was the *World Ethnographic Sample* (1957), which consisted of 565 cultures coded for 30 variables. This was followed by the *Ethnographic Atlas*, a series of installments of codes that appeared in the journal *Ethnology*, founded by Murdock in 1962. These were eventually published together as the *Ethnographic Atlas* (1967). His collected papers appeared in *Culture and Society* (1965). The *Atlas of World Cultures* (1981), Murdock's last publication, produced codes for 563 cultures. In 1968, he created the Cross-Cultural Cumulative Coding Center (known as "The 5 Cs"), which produced codes for a 186-culture sample known as the Standard Cross-Cultural Sample.

George Peter Murdock was born May 11, 1897, on a farm near Meriden, Connecticut, the firstborn child

of George Murdock and Harriet Graves. The young Murdock grew up on the farm, attended local grammar and high schools and then Phillips Academy, Andover, and finally Yale, where he received both the A.B. (1919) and Ph.D. (1925) degrees. While a freshman, he enlisted in the Connecticut National Guard, later becoming a second lieutenant of field artillery. World War I ended before he could be sent to Europe. He attended Harvard Law School but left during the second year. Then he spent a year traveling the world, by the end of which he decided to do anthropology. Franz Boas refused to admit him to Columbia University in 1922 because Murdock was a dilettante, but Albert Keller, a former professor, admitted him as a candidate for the Ph.D. degree in a combined anthropology–sociology program. His dissertation was a translation from German of Julius Lippert's *The Evolution of Culture* (1931). In 1925, Murdock married Carmen Swanson. For 2 years he taught sociology and anthropology at the University of Maryland, and in 1928 he returned to Yale University as an assistant professor in sociology. When a new Department of Anthropology was established in 1931 under Edward Sapir, a famous linguist, Murdock received a joint appointment. He carried out field research with the Haida of the Northwest Coast during the summer of 1932 and with the Tenino of Oregon during the summers of 1934 and 1935. Although his time in the field barely exceeded a year, he urged his students and colleagues to conduct intensive fieldwork. He was appointed chairman of the Department of Anthropology in 1938, and he became a full professor a year later. In World War II, Murdock served as a lieutenant commander (1943–1945) and a commander (1945–1946) in the U.S. Naval Reserve. In 1947, he led a team of field researchers to the island of Truk in Micronesia. In 1960, Murdock became the Andrew W. Mellon Professor of Anthropology at the University of Pittsburgh. In 1972, he was instrumental in founding the Society for Cross-Cultural Research, a professional association that draws its membership explicitly from anthropology, psychology, and the other social sciences. He retired in 1973 at 75 years of age. He and his wife moved to Wynnwood in eastern Pennsylvania to be near his son. After his wife died, he moved to a retirement home. Murdock died March 29, 1985, in Devon, Pennsylvania, at 87 years of age.

Museums of the late 20th and early 21st centuries are commonly defined as permanent nonprofit institutions that serve society by acquiring, conserving, and displaying material so as to provide the public with opportunities for education and entertainment. Whether dedicated to art, culture, history, or natural history, museums often provide people with their first introduction to the field of anthropology. Although museums have become a focus of debate over who has rights to collect, conserve, study, and display culture in material and other forms, museums continue to serve as important resources for both anthropologists and the public.

The origin of museums lies in collections. The word *museum* comes from the Greek *mouseion*, a shrine dedicated to the daughters of Zeus, known as the Muses, who presided over various arts and sciences. In this sense, one of the earliest museums might be the 3rd-century BC Mouseion of Alexandria in Egypt that housed the famed library in addition to

other collections. China might have an even longer history of creating collections, but these were normally private and not open for general study.

Modern anthropological museums originated during the era of European exploration when explorers, such as Christopher Columbus, and later military leaders, such as Hernando Cortez, collected and shipped finds of potential interest to their royal supporters. This initiated a custom of elites acquiring a “cabinet of curiosities” in which they might display a range of natural and cultural specimens acquired at home and abroad. The Ashmolean Museum of Oxford, based on a cabinet of curiosities, opened in 1683 as the first public museum offering a loosely defined “educational” experience for anyone who paid the admission fee.

During the 18th and early 19th centuries, national museums developed in Europe. Although the museums displayed cultural items, the purposes encompassed variations of nationalism, colonialism, and imperialism. Christian Thomsen at the National Museum of Denmark created the “three age system” organizing collections by material type—stone, bronze, and iron—to present a unified national history. The Ethnographic Museum of National Academy of Sciences in St. Petersburg documented the growing diversity of people within the Russian Empire. The Louvre in France originated in collections

nationalized under the French Revolution and the booty of Napoleon’s campaigns that it legitimized by stressing public education. The National Museum of Ethnography in Leiden centered on the P. F. B. von Seibold collections acquired during visits to Dutch colonies and arranged according to cultural groupings.

Throughout the 19th century, holders of collections followed the trend set by national museums and transformed cabinets of curiosities into permanent public institutions run by academics for purposes of research and education. Although the field

of anthropology was still in its infancy in both Europe and the United States, museums served as incubators of the field before the discipline became firmly established in colleges and universities.

The most common variety of modern museum is that dedicated primarily to collections. Most often, these are housed in special facilities designed especially for the collection and include areas devoted to display as well as extensive areas dedicated for storage, conservation, and research. This variety of museum tends to have the largest and most diverse collections of ethnographic and archaeological materials of interest to anthropologists. Many of the world’s most famous museums fall into this category and include museums of the Smithsonian Institution, the British Museum in London, and the Field Museum in Chicago. Most university-run museums, such as those at the University of California, Berkeley, Harvard University, Yale University, and the University of Pennsylvania, are also of this type.

A second variety of museum is focused on historic locations, including house museums and interpretive centers. House museums focus on preservation of an historic structure often associated with a particular individual and time period. Collections of these institutions tend to be limited because the focus of the activities tends to be on the structure and its furnishings as they represent or reflect an historic

individual. The Harriet Tubman Home in New York and the Hermitage Museum in New Jersey are of this variety. Interpretive centers are museums associated with particular historic locations, including archaeological sites. Like house museums, interpretive centers are narrowly focused on specific time periods and locations.

A third variety of museum of interest to anthropology is the living history museum. These often consist of large venues with multiple buildings. Unlike the static presentation of information in collection-based house museums and interpretive centers, living history museums dynamically seek to entertain and educate through the use of live interpreters who interact with the public and sometime demonstrate traditional crafts and skills. Plimoth Plantation in Massachusetts and Colonial Williamsburg in Virginia are prime examples.

With the advent of the Internet, anthropology has also encountered the virtual museum. Virtual museums are digital collections of images and information. Virtual museums often represent the actual collections of a particular institution or set of institutions, such as the Virtual Museum of Canada, where the virtual museum is an opportunity to extend the educational reach of many of its participant institutions. Virtual museums can also extend the educational capacity of an institution beyond its actual collections, as with the Emuseum of Anthropology maintained by Minnesota State University at Mankato.

Since postmodern theorists of the late 20th century began to question the construction of knowledge, museums have become a locus of debate. These debates focus on issues of access, rights, and voices. The access debate concerns not only the physical and linguistic accessibility of museums but also the economic barrier imposed by admission fees. Although fees are generally viewed as essential to the financial health of museums, they also act to exclude those on the economic margins who might benefit from a museum's educational content.

Debates over rights and voices are illustrated by the contention over the Native American Grave Protection and Repatriation Act (NAGPRA). This legislation restores Native American rights to cultural materials, many of which have been held in museum collections. Through NAGPRA, Native Americans have challenged the right of museums to collect, study, and display materials and have opened debate about who should interpret culture—anthropologists or indigenous peoples. Although museums have retorted that they have better facilities for storing and conserving objects and can provide access for more people than can indigenous groups, many museums now accept the importance of indigenous voices in describing and explaining cultures to the public.

Music

Music is an integral part of culture. Not only is it interesting in itself and an object worth studying as is any other part of culture, but it also sheds light on various cultural processes. Anthropological interest in music, moreover, is not limited to so-called “primitive” or “folk” music any more than anthropology itself is limited to the study of “simple” societies and cultural forms. Just as anthropology studies complex societies, among others, and complex ways of life, so too does it study all types of musical expressions.

Ethnomusicology, which is the specific branch or concentration of anthropology concerned with the understanding of music in culture, studies music within human society and culture. It is concerned in particular with the way in which music symbolizes the way of life of a people. It studies things such as social transformation and power as expressed through music and its role in sociocultural life.

The anthropological study of music is concerned with understanding music as a cultural expression.

Ruth Finnegan argued that understanding music is critical to understanding a culture itself. She wrote,

Any ethnography should obviously include basic information such as relationship, social organization, ways of life, working assignment, economic and political systems, religion, basic language characteristics, historic background, and perhaps some lesser attention to visual and plastic arts, but *marginal* and *specialized* aspects of culture such as musical performance or oral literature could be set aside as minor issues.

An anthropology of music looks at the web of relationships in which music finds itself and is used. Music is part of many social relationships. It is often part of children’s games, marriages, parties of all sorts, formal occasions, and many other events—scheduled or not.

Music is certainly part of ritual, both religious and secular. It provides an entrée into understanding these significant aspects of social life. The type of music for these events, the ways in which they are performed, and the manner in which music relates various elements to one another add to the cultural understanding of a society.

However, David Coplan argued that “music shouldn’t be studied within its context but as a context itself.” Coplan called our attention to the study of music comparable to the study of language. Through studying music in context, he maintained that anthropologists will approach a better understanding of culture itself, looking at the manner in which symbols work to represent meaning.

Nevertheless, most anthropologists who look at music do so within social contexts. They are interested in the meaning it has for specific groups of people at particular times and places as well as its general cultural relevance. Allan P. Merriam argued for the necessity to understand the contexts in which people make and use music and promoted a broader anthropological approach to music and its role in culture. Alan Lomax attempted to demonstrate how the structure of a people’s music results from its social and cultural structure and function, an approach

Source: © iStockphoto/George Argyropoulos.

that Joseph Nketia criticized as too mechanical. Nketia found that it ignores the complexity of a society's culture.

Charles Keil is one of the key figures in the development of the anthropology of music. He helped anthropologists to focus on the importance of popular music in understanding culture. Keil studied entertainers, bluesmen, who were popular entertainers and not folk musicians, as they were understood to be during the 1960s. He demonstrated the value to cultural understanding of taking these musicians seriously and understanding their role on their own terms.

Keil took the anthropology of music into urban areas but did not neglect its relationship with music in the forests of Nigeria as well. He also tied music to other aspects of culture, including literary culture. He saw music as related to the literature of a culture, emphasizing the holistic aspect of anthropological understanding. Certainly, the fieldwork that he did in Nigeria reinforced this holistic perspective.

Keil's study of the music of the Tiv of Nigeria and their unique song culture resulted in the award-winning *Tiv Song* (1979). The book is a passionate study of the Tiv people and the role of music in their culture. It is a model for the anthropology of music. Keil poured some of that same passion into his study of other kinds of popular music, including Greek music and polka.

Alan Merriam defined ethnomusicology as "the study of music in culture." He also stated that it was "the study of music as culture." The anthropology of music has attempted to combine both approaches. Merriam's work reoriented the field to concentrate on the study of music from the point of view of the people who made it. He encouraged anthropologists to look for the meaning and purpose that music had for the people who created and used it. He pushed people to understand music in culture and music as human behavior. Anthropology is still working out the implications of this model, as Keil's work demonstrates quite clearly.

Muslims, literally those who submit to God's will, are the community of more than 1.3 billion practitioners of one of the world's major and fastest growing religions, Islam. Although Islam began in the Middle East in the Arabian Peninsula, the largest populations of Muslims today live in Central, South, and Southeast Asia in countries such as India (with more than 100 million Muslims) and Indonesia (with more than 160 million Muslims). Islam also is expanding in Africa, Europe, and the Americas. Despite their diversity, Muslims share a belief in one God who sent messages to humankind through His prophets, the last of whom was Muhammad. Anthropologists have contributed to the study of Muslim communities around the world through research on topics such as economic strategies, sectarian and ethnic divisions, and gender relations.

Historical Background

The prophet Muhammad was born in Mecca, a prosperous Arabian town, in 570 AD. At 40 years of age, while meditating in a cave near Mecca, Muhammad received revelations from God and began reciting

these to the people of Mecca. The words comprise the Quran, Islam's holy book and the last, final, perfect revelation from God, according to Muslims. The Quran mentions many people also found in both the Old Testament and New Testament, including Adam, Noah, Abraham, Joseph, Moses, David, Solomon, John the Baptist, Mary, and Jesus. Following persecution by some Meccans, Muhammad and his followers migrated to Medina, where they formed a community of faith, the *umma*. The Hijra, or emigration to Medina, in 622 marks the first year in the lunar Islamic calendar. The Muslim community returned to Mecca in triumph in 630, gaining many more adherents. During the early years after Muhammad's death in 632, Islam spread rapidly through North Africa and north and eastward in Asia to many groups in addition to the Arabs.

The orthodox majority of Muslims, comprising 90% of the total, are known as Sunnis (from the word *sunna*, Arabic for "customary conduct," referring to the practices Muhammad observed). The Shia, whose origin comes from disputes over appropriate leadership after Muhammad, comprise a minority of approximately 10 to 15%; however, they control the state in Iran and are the majority in Iraq. Shiism has been divided into numerous sects since the eighth century. Most are known as Imamis or Twelvers because they accept 12 imams or leaders, from the 1st, Ali, to the 12th, who is believed to have hidden himself away only to return later to restore justice prior

to the end of the world. Others include the Ismailis (Seveners) and the Zaydis, both of whom recognize imams who are not accepted by the Imamis.

Anthropological Studies of Muslims

During the last half of the 20th century, anthropologists conducted research on many diverse Muslim communities. Because of an emphasis on economic lifestyle and subsistence pattern, the ethnographic literature often divides people into three types: pastoralists, village agriculturalists, and urbanites. Although animal husbandry, agriculture, and commerce are interdependent and have formed an integrated system for thousands of years in Asia and Africa, and people frequently change from one lifestyle to another, ethnographies tend to treat each type in isolation. Nomadic pastoralists, comprising approximately 1% of the Middle East's population, were studied disproportionately by anthropologists, especially before the 1970s.

Studies of pastoralists describe two patterns of animal herding: vertical or transhumant (with seasonal movement up and down mountains) and horizontal (with movement following water and other resources). The internal integration of kinship and politics also was a major theme in anthropological writing, as was the conflictual relationship between pastoralist tribes and state organization. In many anthropological monographs about pastoralists, people are described as following their own customs and having little familiarity with normative Islam.

Dry farming and irrigation agriculture have ancient origins in Asia and Africa. Many village studies emphasized traditional land tenure systems and the mechanisms through which access to land and water was regulated. Recent studies have also accounted for the historical and economic transformation of villages, the changing nature of elites, and the expansion of government influence. Anthropologists have written less

about city life than about pastoralism or village agriculture. Studies of urban neighborhoods focus on ethnicity, social class, and culture change.

As U.S. foreign policy increasingly focused on the Muslim world during the 1980s and 1990s, some anthropologists sought to include broader policy implications in their analyses in addition to the particularistic studies of tribe, ethnic group, and village that dominated the ethnographic literature. M. Nazif Shahrani and Robert Canfield's edited volume, *Revolutions and Rebellions in Afghanistan*, brought together articles by a variety of experts who conducted fieldwork in Afghanistan, demonstrating both the commonalities and differences of disparate groups' responses to governmental change there.

Formal studies by various researchers have been complemented by personal accounts of fieldwork experiences. In *Guests of the Sheik*, not only did Elizabeth Fernea describe her interaction with the women of an Iraqi village, but she also accompanied them on a pilgrimage to important Shia sites and provided a unique description of the reenactment of Husayn's martyrdom on the 10th of Muharram. In addition, as part of the development of postmodern ethnography and experiments with writing, various forms of dialogue and emotional encounters with Muslim informants have become important to the general literature in anthropology. Paul Rabinow's frank description of his Moroccan fieldwork detailed his interpersonal difficulties and frustrations in one such account.

The influence of feminism in the United States and Europe during the 1970s sparked interest in studies of gender, women's roles, and women's status in the Muslim world. Early studies emphasized the separation of men's and women's lives, the former in the public realm and the latter in the private realm. Notions of honor and shame also were linked to men and women, respectively. In addition to the examination of women's lives, some ethnographers paid greater attention to children because socialization was another avenue for examining gender identity and roles. Later studies examined influence and agency exercised by women within their own communities and over men. Multiple ideologies and discourses allow women, as well as men, to be poets and warriors.

MUTANTS, HUMAN

Mutants, human or otherwise, historically were defined as those individuals whose appearance or functional capabilities lay beyond the boundaries of the perceived "normal." Synonymous words include *monsters*, *freaks*, and *paranormals*. Today the terms *mutant* and *mutation* refer more commonly to specific alterations at the genetic level that give rise to our full spectrum of phenotypic diversity, including infinite minor variations such as eye color and nose shape. In the strict biological sense, all humans are mutants. This entry is limited to a review of the greater extremes of morphological variations such as the dwarfs, hunchbacks, conjoined twins, savants, and others who have provoked fascination, fear, and the interest of scholars from the earliest epoch.

Originally, the study of the monstrous was known as teratology. More recently, this term has been limited to mean the study of birth defects, thereby removing elements of the mythical or magical. Importantly, however, not all mutants arise merely from congenital events. Freakish forms may also result from accident (any disfiguring trauma) or illness (advanced leprosy). They may be a result of toxic exposures to chemicals (phocomelia from thalidomide) or excess radioactivity. Freaks may also be self-made via procedures such as elective surgery and tattooing. They may also be created unexpectedly, as from an operative procedure gone awry or via the new and unpredictable frontier of transgenic manipulations.

What, then, does it mean to be "abnormal"? The definition is both chronologically and culturally dynamic. The contexts of religion, science, and philosophy all inform the socially constructed ideas of

deviance. Thus, the history of societal attitudes toward mutants reflects the myriad cultural influences that are so important to anthropology.

Antiquity

Monstrous races and beings have been cited since antiquity. Greek, Scandinavian, and Asian mythologies rendered tales of beasts with fantastic skills and/or outlandish proportions. Debate over the origins of these creatures has often focused on whether the images might be based on some remote fact, on pure fancy, or perhaps on both. Pliny the Elder, in his influential book *Natural History*, catalogued hundreds of bizarre creatures culled from the existing texts of the times. The Cynocephali, for example, were a race with dog-faced heads on human torsos. Could these animals have derived from crude descriptions of real humans with exaggerated facial slopes, hypertrichosis, or elongated noses? Alternatively, many of Pliny's other eclectic entities might well have sprung simply from a vivid imagination and an interest in a good story.

During this pre-Christian era, most true birth deformities were ascribed to the supernatural, and explanations abounded. Abnormal infants could be thought to be the result of an inauspicious copulation, perhaps involving the descent of an incubus, or merely of bestial relations. Even if the fertilizing union were pure, however, a developing fetus might be altered, positively or negatively, by environmental influences such as eclipses, comets, and floods. A related concept, propagated through the next several centuries, was the theory of maternal impressions. According to this theory, a trauma or fright to the mother would then transfer to the embryo. Even self-induced maternal imagination or dreams might have an effect. Later investigators soon discounted these beliefs, although the understanding of teratological nutritional and toxic exposures (e.g., thalidomide, alcohol) has advanced.

Middle Ages

The emergence of the powerful influences of Christianity, and subsequently of Islam, led to religious explanations for the monstrous. A polydactylous newborn might be considered demonic but by that time might also be considered a "prodigy" and taken as a sign of God's universal wisdom and dominance. Theological

arguments about predeterminism, as espoused by St. Augustine, had obvious implications for embryology. Galen's writings during this time had special influence among both Arab and European thinkers by implying that nature represented God's will and purpose, so that a mutant could be considered divine. Deformity came to be interpreted as either sacred or profane, or as either heroic or deviant, based on the cultural context.

This period also saw the idea of freaks as religious or political omens. Perhaps the most famous example is the monk-calf as published by Martin Luther and Philippe Melanchton during the 1500s. Their monk-calf was possibly a fabrication, but it was nonetheless widely heralded as a portent of the corrupt decline of the Roman Catholic Church. A few years earlier, the fall of the besieged Italian town of Ravenna had been attributed to the birth of a deformed infant, the notorious Monster of Ravenna. Armand Leroi suggested that the monster might have been an example of what is today understood as Robert's syndrome, but whatever the true condition, the implication for the city's defense was clear. Both of these incidents helped to spread the idea of monsters as religious symbols among the population at large.

Enlightenment

The Renaissance brought to Europe a new sense of objectivism that allowed dramatic breakthroughs in teratology. Scientists and natural philosophers began to seek out and collect mutants. The increasing skills and curiosity of anatomists led to the first comparative dissections. The well-known French surgeon Ambroise Pare published *De Monstres et Prodiges* in 1573. He made one of the first attempts at systematic categorizations, although his classifications included both religious and natural domains. Many other descriptive tomes during this period allowed the mutants to be increasingly interpreted as variations within the sum of nature rather than as exotica from beyond. The emergent concept of humanism also began to reduce the religious and symbolic burdens of deformity.

Industrial Age

Scientifically, the study of mutants was restructured at the turn of the 18th century by the investigations of Etienne Geoffroy Saint-Hilaire. This French anatomist

performed several experiments to reproduce deformities by various means and correlated his theories with numerous dissections. The major contributions of his work were twofold. First, he initiated a rigorous taxonomic approach to his subjects that was carried out further by his son Isidore. Second, because he was a contemporary of Chevalier de Lamarck, Etienne's ideas about biological development corresponded with the concept of transformism, presaging Charles Darwin and the broader controversies of evolution.

In the social context, the industrial age was also allowing mutants to acquire a new identity as entertainers. As early as the 1500s, freaks could be either purchased or paid by eager intellectuals. The market for paranormals subsequently grew and was exploited in the West by people such as P. T. Barnum. Barnum skillfully sought out mutants and promoted them to the masses. He made household names out of Prince Randian, General Tom Thumb, and many others. The sideshows galvanized the public's sense of mystery and wonder, and Barnum capitalized on his ability to equate strangeness with fear. As a consequence, he helped to perpetuate a powerful stigma of disability, even though many of his employees lived to enjoy both respect and wealth. The effort to bring the disabled back to the community mainstream continues today and has been the basis of many legal protections in the United States such as the Americans with Disabilities Act (ADA) and the Individuals with Disabilities Education Act (IDEA).

The economic opportunity afforded by the performance stage also led to a rise in the so-called "fake freaks." These were able-bodied individuals who masqueraded as mutants in return for cash. Many viewers became suspect of the cheap ruses being employed, and the popularity of many shows suffered. The gradual disappearance of the freak shows followed, ostensibly due to public disgust and concern over exploitation of the performers. Yet many regulars had few meaningful options to earn a living. Critics have asked whether or not the true impetus for closures was merely the need to remove a taboo that modern audiences were uncomfortable in viewing.

The convergence of the new science of genetics with the growing debate of evolutionary theory set the stage for the eugenics movement of the early 20th century. Eugenics became especially popular in Germany, Britain, and the United States. In this context, the mutants were by this time evaluated on the

basis of their potential contribution to the "gene pool" and overall betterment of society. Freaks increasingly became a marginalized group and were even persecuted in the name of "negative" eugenics. Laws were passed to limit reproduction, immigration, and intermarriage outside of an Anglo-Saxon ideal. Eventually, by the late 1920s, the racist connotations of the movement had been discredited and the more onerous restrictions had been lifted.

Modern Era

The explosion of genetic science has provided the latest paradigm for teratology. Many phenotypes can now be explained by genomic models, even if the mechanism of change still is not completely understood. Global increases in mobility and communication have lessened the importance of cultural freaks but also have raised new forums for examination. For instance, how do some humans attain previously unknown levels of performance? Why can some people climb to the summit of Mount Everest without supplemental oxygen, consistently hit high triple C on the trumpet, or speak 22 languages? Answering these questions about "functional mutants" involves the sorting of physiological characteristics from training effects or from features of mental discipline. Yet the causal web is no less complicated than the search for genetic influences, for example, on a man with fragile X syndrome.

Many cultures now also contend with rising trends of self-made freaks. The availability of potent drugs, such as anabolic steroids and synthetic growth hormone, has encouraged the pursuit of being taller, stronger, and/or faster. Sophisticated surgical techniques mean that there is always some other feature that can be altered. The French artist Orlan has undergone serial cosmetic surgeries in the name of art, employing the operating theater as her artistic medium. Instead of mutants such as Joseph Merrick (the "Elephant Man") struggling to live within the societal norms, we see average people going to great lengths to make themselves stand out in a society. More than ever, the line between the normative and the exotic has blurred and continues to raise questions about the cultural values of form, beauty, and diversity.

MUTATIONS

A genetic mutation is a spontaneous random change in the chemistry of DNA. The word *mutation* is related to the Latin verb *mutare* meaning “to change.” Mutagenesis is the process by which mutations arise, and a product of mutagenesis is sometimes referred to as a mutant. Science fiction frequently has popularized mutants as negative beings, but in reality genetic mutations actually can have positive, neutral, or negative results. During the past few decades, DNA research, with much attention to genetic mutations, has greatly expanded as a research area.

Some mutations are not only positive but also crucial because if there were no mutations, there would be no changes in the chemistry of DNA and, hence, no evolution. Of the four evolutionary forces important to the survival and distribution of genes (mutation, natural selection, genetic drift, and gene flow), only mutation is a source of new genetic material. Natural selection does help to increase more favorable mutations in the gene pool (as well as remove less favorable mutations), whereas genetic drift and gene flow affect the distribution of genetic variations.

Mutations can occur in all cells in the body, but only mutations in the germ cells (sperm and eggs) can be inherited and perhaps passed on to future generations. Although mutations in nongerm cells, somatic cells, are frequent and occur throughout life, they are not inherited. These mutations affect only a relatively small number of the billions of somatic cells

and usually are neutral and insignificant. However, some somatic mutations can be very serious. A mutation can cause a cell to grow and divide uncontrollably, leading to a tumor and possibly cancer.

During human reproduction, the four building blocks of DNA are adenine, cytosine, thymine, and guanine. They are referred to by their initials, ACTG (the language of DNA), and usually are copied exactly for the next generation. But occasionally an error or mutation occurs. An analogy may be made between a typist making a simple random retyping error and the genes making a copying error with these four letters, with varying consequences in both cases. For example, an original police report might state that cake was in the bag that the suspicious person was carrying, but the retyped report that the judge sees might state that coke was in the bag. Simple errors can have serious consequences. Because some genetic mutations can have very serious consequences, such as disease or death, natural selection has ensured that the number of mutations remain low.

In addition to spontaneous natural mutations, external agents, called mutagens, also can cause mutations, referred to as induced mutations. The two major mutagens are radiation and chemicals. For example, ultraviolet radiation from the sun is mostly absorbed by the ozone layer, but as the ozone hole grows, the odds of being afflicted with skin cancer and melanoma increase. Radiation from X rays also causes controversy. Toxic chemicals from cigarette smoke, many industrial pollutants, and an increasingly recognized number of other sources also can cause harmful mutations. As the overall mutation rate in DNA from mutagens is increased, the odds of a mutation occurring in a cancer-causing gene are increased. The number of known factors that can cause mutations is increasing as more research is being conducted. For example, it has been suggested that increasing the temperature of the male testes, such as can occur by wearing tighter pants, can also increase the mutation rate.

Especially since the 1960s, more understanding of the importance of mutations has led to more interest in medical anthropology. Controlling communicable diseases, making advances in reproductive technology, and understanding the effects of environmental destruction on possible medical advances are examples of ways in which anthropology intertwines with genetic research.

Research advances in genetic mutations have affected previous anthropological explanations of

ancient history in different parts of the world. For decades, physical anthropologists who accept the multiregional school of history have said that historical changes in human physical characteristics are the result of slow adaptation happening simultaneously at different rates in different parts of the world. With support from research on mitochondrial (female) DNA mutations, replacement school researchers have been able to estimate the number of generations it takes for a mutation to occur and, therefore, have been able to go backward in time to estimate the time period of major migrations and settlements in different parts of the world. Using their dates, they argue that mutational changes could not have occurred within the time periods suggested by the multiregionalists.

Genealogy, using the anthropological concept of kinship, also has benefited much from the study of mutations. Mitochondrial DNA mutates too slowly to provide much help for recent genealogical knowledge for females on female lines, but it has been used to classify nearly all women into one of seven genetic groups in the world, referred to by Bryan Sykes as the seven daughters of Eve. The male Y chromosome mutates more rapidly. Using the male Y chromosome to study how closely two males are related, for example, one can count the number of mutations between two males to determine how many generations one needs to go back to find the most recent common direct male ancestor (MRCA). For example, if two males match on 12 of 12 markers (positions tested on the DNA chain), there is a 50% probability that their most recent common direct male ancestor is 500 years in the past.

Forensic anthropology, a specialization area within physical or biological anthropology, continues to put much emphasis on osteology or skeletal biology. But it also has benefited much from recent DNA research based on mutations. Similar to genealogical matches, DNA from a suspect is matched with DNA results from a number of people who have been tested to see whether the DNA of a suspect matches the DNA of any of the people tested or vice versa.

The relationship among linguistics, archaeology, and differential DNA distributions as related to national, ethnic, and other groups received major attention during the 1990s with the work of Luigi Luca Cavalli-Sforza.

DNA research is starting to make major advancements. As academicians studying ancient migration and settlement patterns, or as applied anthropologists

concerned with medicine, forensics, or genealogy, anthropologists can make major contributions.

MYTHS AND MYTHOLOGY

Myths may be classified as traditional stories that deal with nature, ancestors, heroes, and heroines or supernatural beings that serve as primordial types in a primitive view of the world. Myths appeal to the consciousness of a people by embodying its cultural ideals or by giving expression to deep and commonly felt emotions. These accounts relate the origin of humankind and a perception of the visible world; the character, attributes, and functions of the ancient gods; and stories concerning an individual, an event, or an institution. The systematic collection and study of myths is termed *mythology*. Mythological research into the earliest literary records of the ancient world is essential for understanding the religions and philosophies of these peoples. Equally important, the study of mythology enhances our appreciation for the art and literature of the classical and modern eras.

Why Were Myths Created?

It is no wonder that myths evolved in primitive cultures when people were faced with impersonal, inexplicable, and sometimes awesome and/or violent natural phenomena and the majesty of natural wonders such as the sun, the sky, the mountains, and the sea. In comparison with these wonders, humans felt dwarfed and diminished. As a result, they bestowed

extraordinary human traits of power and personality to those phenomena that evoked human emotions most profoundly. The origin of the world, the miracle of birth, the finality of death, and the fear of the unknown compelled early humans to create deities who presided over the celestial sphere. In time, every aspect of nature itself, human nature, and human life was believed to have a controlling deity.

These gods, goddesses, and cultural heroes and heroines, as well as their stories, served and continue to serve a multitude of purposes. Initially, myths of cosmogony illuminate the origin of humankind. Virtually every culture embraces a creation myth. Myths explain the beginnings of customs, traditions, and beliefs of a given society and reinforce cultural norms and values, thereby depicting what that society regards as good or evil. Myths assist in defining human relationships with a deity or deities. Judeo-Christian-Islamic societies have established a supreme power, a father figure, whereas the Norse tradition restricts the power and purveyance of the gods. Finally, myths help to dispel the fear and uncertainty that is part of the human condition. Fear of the elements may be explained by the activities of the gods. Fear of failure is overcome by reliance on them. Fear of death is often explained as the passage or transition to another dimension or to another domain. Simply stated, myths are a symbolic representation reflecting the society that created them. Although unjustified and unjustifiable, myths take the raw edge off the

surface of human existence and help humans to make sense of a random and threatening universe.

Universal Themes

The themes of great myths are universal, and they center on ancestors, deities, heroes, heroines, and nature. Mythic themes have evolved in every culture, are unique to each culture, and yet often bear striking similarities. Myths are seldom simple and never irresponsible. Esoteric meanings abound, and the proper study of myths requires a great store of abstruse geographical, historical, and anthropological knowledge. The stories underscore both the variety and continuity of human nature. One of the most intriguing characteristics

of myths is the way in which they have been transmitted, adopted, and adapted by successive cultures. The abiding interest in mythology lies in its connection to human wants, needs, desires, strengths, and frailties. By their nature, myths reveal the interwoven pattern of circumstances that are beyond the control of the mortal and the immortal.

As we delve further into the world of myths, we enjoy the subtle and dramatic ways in which myths pervade societies, unveiling universal themes, moral direction and inspiration, and how particular myths mirror the society in which they were created and developed. Myths are decidedly human in origin, and they speak of fire and ice, wind and rain, selfishness, anger, jealousy, courage, love and hate, hope and despair. Ironically, it is the human ability to make myths, and the very need to do so, that ultimately sets humans apart from other inhabitants of the earth.

Myths may be drawn from any era and any geographical area. For this treatise, we examine components of Greek and Roman mythology, Norse and Teutonic (Germanic) mythology, Oriental mythology, and the commonalities among these and several other cultures.

Greek Mythology

To people of Western cultures, the most familiar mythology outside of the Judeo-Christian culture is

that of Greek and Roman mythology. The mythology of ancient Greece and Rome stemmed from the human desire to explain natural events and the origin of the universe. The myths chronicle Zeus and his brothers, Poseidon and Hades, who exacted control of the universe from their father, Cronus, and the Titans, a powerful race of giants. Cronus himself had wrenched control from his own parents, Uranus (heaven) and Gaea (earth). Great epics of war and peace and proud heroes and courageous heroines, who represented the basic cultural values of the Greek people, were recorded. Men and women alternately worshipped and feared a ménage of gods and goddesses who traditionally resided on Mount Olympus, attributing failure and defeat to the wrath of the gods and attributing success and victory to the grace of the gods.

Women offered great homage to Hera, the wife of Zeus and queen of the gods, whose name means “splendor of heaven.” Hera, the mother of some, but not all, of Zeus’s many offspring, was implored by women who were about to give birth to numb the pain of labor and to favor them with healthy and beautiful infants. Because she had been betrayed by Zeus, Hera, who wore golden sandals and sat on a golden throne, deigned to destroy her husband and kill his consorts. Ironically, Hera was worshipped as the protector of marriage. Named Juno by the Romans, Hera is often depicted holding a peacock.

Roman Mythology

Much of Roman mythology had its roots in Greek mythology, although Jupiter and Mars were part of the Roman tradition long before the Romans interacted with and eventually conquered the Greeks. Subsequent to 725 BC, the Romans adopted many Greek deities, renaming them and making them their own. In both Greek and Roman mythology, realms of the universe are delineated. The Greeks and Romans saw the cosmos in terms of the skies, the earth, the seas, and the lower world. Jupiter (Zeus) ruled the skies from atop Mount Olympus, where he controlled the movement of the sun, the phases of the moon, and the changes of the seasons. When Jupiter, the fairest and wisest of all immortals, was outraged, he hurled lightning and thunderbolts down on the earth. Neptune (Poseidon), the second most powerful god, ruled the seas, and Pluto (Hades) ruled the lower world. Pluto, the god of wealth, drove a black chariot

powered by six onyx-black horses and was guarded by Cerberus, the three-headed dog.

As we read these highly entertaining and often spiritually uplifting myths, we learn a great deal about human nature and of our debt to Greek and Roman cultures. Modern language is imbued with references to their extensive pantheon and the heroes and heroines of their civilizations. Consider, for starters, the names of the planets, the stars, and the galaxies. Even today, in our struggle to survive, Greek and Roman myths help people to better understand humanity’s obedience to a higher power, the relationships of men and women to one another, the power of love and friendship, the horror of war and natural catastrophes, and the strength of parental devotion.

Norse and Teutonic (Germanic) Mythology

Germanic mythology refers to the myths of people who spoke Germanic dialects prior to their conversion to Christianity. These ancient Germanic people from the continent and of England were illiterate. Most of what we do know about the mythology and beliefs of that era comes from literary sources written in Scandinavia and then transcribed into the Old Norse language of Iceland from the 12th to 14th centuries. Two collections of verse, known as the *Eddas*, exist. The earliest, the *Elder Edda* or *Poetic Edda*, contains the earliest Norse mythology, whereas the *Younger Edda* or *Prose Edda* was written by Snorri Sturluson around 1220 AD. In the *Prose Edda*, Sturluson combined a variety of sources with three earlier poetic accounts of the origin of the world to create a wholly representative mythology.

In the *Prose Edda* version of the creation, all that originally existed was a void called Ginnungagap. To the north of the void was the icy region of Niflheim, and to the south of the void was the sunny region of Muspelheim. Warm breaths from Muspelheim melted the ice from Niflheim, and a stream of water flowed into the void, from which emerged the giant, Ymir, ancestor of the Frost Giants. Created from drops of the melting ice, Audhumbla, the cow, nourished Ymir and was nourished herself by licking salty frost- and ice-covered stones. The stones were formed into a man, Bori, who was destined to become the father of Odin, Vili, and Ve. The brothers slaughtered Ymir and created the earth from his flesh, the mountains from his bones, the sea from his blood, the clouds from his brains, and the heavens from his

skull. The heavens, according to the *Prose Edda*, were balanced by four dwarfs—Austri, Westri, Nordi, and Sudri—the directions on a compass. Sparks from the fireland, Muspelheim, became the stars of the sky. This newly created land, named Midgard, was to become the somber home of mortal humans. Even in Asgard, home of the gods, the atmosphere was grave and the only hope was to face disaster and fight the enemy bravely to earn a seat in Odin's castle, Valhalla. As with so many similar myths, Norse mythology reflected the attitude of the culture: In death there is victory, and true courage will not be defeated. Some of these mythic themes are represented in Richard Wagner's music-drama tetralogy, *Der Ring des Nibelungen*.

Oriental Mythology

The myths of India, China, and Japan are highly complex and sophisticated. They differ from Greek, Roman, and Germanic mythologies in that, rather than venerating anthropomorphic deities, the structures of these deities are usually polymorphic, intricately combining human and animal forms. The gods and goddesses of the Hindus take extraordinary human forms with numerous heads, eyes, and arms. During early times, deities in Chinese and Japanese myths were more animistic, but these myths were supplanted by mythologies derived from the three great religions: Taoism, Confucianism, and Buddhism, with Buddhism having been brought to China from India in 300 BC. Shinto, the religion indigenous to Japan, borrowed much from Chinese mythology, resulting in a tradition that paralleled that of the Buddhist pantheon. Notably in Asian cultures, two or more religions may be observed simultaneously because they are less eschatological but more ethical or philosophical in emphasis, showing people how to live rather than what will happen to them on their demise. We may deduce, then, that oriental myths not only explain the origin of the universe but also deal with distinctive aspects and commonly held cultural values of each civilization.

During ancient times, throughout history, and even today, the family is considered to be a critical part of oriental society and culture. Honor and obedience to one's parents is related to ancestor worship. During the Han period in China, emperors set up shrines for their ancestors because they believed that spirits could bring blessings to them and to their families. In general, oriental myths connect the actions of deities and other supernatural beings to the everyday actions of

men, women, and the natural world around them. Individual gods protected the family, the home, and the country and represented the sun, the moon, and the planets. Myths describe how the islands of Japan were created and deliberately located by the gods in the very center of the world. The two main books of the Shinto religion are the *Koji-ki* and the *Nihon-gi*. The *Nihon-gi* explains how all of the emperors of Japan are directly descended from the Sun Goddess. Today, the rising sun is symbolized in the Japanese national flag.

Commonalities

What the disparate mythologies from all over the world have in common is their heartfelt desire to explain the origin of humankind and to validate its existence. We are searching to satisfy the very human need to explain our relationship with the powerful and mysterious forces that drive the universe. Throughout the world, myths reflect those themes that deal with nature, supernatural beings, ancestors, or heroes and heroines. In Africa, where myths have been preserved mainly through the oral tradition, the natural elements are immortalized through myths. Many versions of creation stories abound. The Dinka of Sudan believe that the first man and woman were made from clay and put into a tiny covered pot, where they grew to full height. Australian Aboriginal mythology deems that their community and culture were created during dreamtime, "the time before time" when spirited creatures came from the sky, the sea, and the underground to generate mountains, valleys, plants, and animals. We are familiar with the Great Spirit myth of North American Indians and the import that Native Americans reserve for their ancestors. The Aztec people of South America were polytheistic and offered sacrifices to appease their gods. Huitzilopochtli, the great protector of the Aztecs, was portrayed in the form of an eagle, and it was he who deemed where the great pyramid would be built as "the heart of their city and the core of their vision of the universe." From Ireland comes a myth about Cu Chulainn, a hero who could change form to oppose evil forces. A Polynesian myth from the islands of the Kanaka Māori people centers on Maui, who brought the gift of fire to his people. In ancient Egypt, from pharaohs to peasants, each individual had a god or goddess corresponding to his or her place in society.

As we can perceive, during every era and in every geographical area, myths have evolved as nearly sacred literature devoid of theology. Each myth is

unique to a culture, particularly to its beliefs and values. Myths are, in themselves, monuments reflecting the precariousness of human existence.

NAPIER, J. R. (1917–1987)

John R. Napier was a British anatomist and primatologist renowned for his comparative studies of fossil primates and early hominids from Africa, and for his pioneering work on primate locomotion.

After medical training at St. Bartholomew's Hospital in London, Napier served as a surgeon in its orthopedic unit. From 1946 to 1967 he taught anatomy at various teaching hospitals and institutions in London, and during this period he became increasingly interested in applying his anatomical training to questions of primate evolution and functional morphology. His initial papers focused on the anatomy and function of the human hand and foot, and this culminated in his landmark contributions on the prehensile movements and grip types of the hand, published in the mid-1950s and summarized in his excellent popular book *Hands* (1980). In 1959, he turned his attention to the fossil record, with functional analyses of the forelimb of the early Miocene ape *Proconsul* and early hominid metacarpals from the South African Pliocene site of Swartkrans. This was followed by research on the postcranial remains of early hominids recovered by Louis Leakey from Olduvai Gorge in Tanzania. In 1964, in collaboration with L. S. B. Leakey and P. V. Tobias, Napier described a new species of hominid, *Homo habilis*, from Olduvai, which constitutes the earliest representative of the genus *Homo*. Napier's interpretation of the prehensile abilities of the species, based on his study of the fossil hand bones, was the basis for the Latin name, which means "handy man." During the 1960s and early 1970s he published a series of influential articles on primate locomotion, a field of investigation that he pioneered, including papers on the classification of primate locomotion, prehension and opposability of

the hand, brachiation, and bipedality. In 1967 he coauthored the *Handbook of Living Primates* with his wife Prue Napier, which represented an important synthesis of the literature on primate taxonomy, biology, and behavior. This was followed in 1985 by their successful updated compendium, *The Natural History of the Primates*.

From the early 1960s onward, Napier was responsible for organizing the first primate biology research and training programs in the UK, as well as at the Smithsonian Institution in Washington, D.C. In 1967, he became the founding president of the Primate Society of Great Britain, the first such organization in the world. In addition to his specialist scholarly contributions, he was a successful and enthusiastic popularizer of science, as a radio and television personality and as writer. His books *The Roots of Mankind* (1970), *Bigfoot* (1972), *Monkeys without Tails* (1976), and *Hands* (1980) demonstrate his abilities in this regard, as well as the breadth of his interests and expertise in primate evolution and comparative anatomy.

NARMADA MAN

The discovery in 1982 of a fossilized skull in the central Narmada valley in Madhya Pradesh, India, provides the first scientifically recorded evidence of human skeletal remains from the Indian subcontinent dating to the late Middle Pleistocene of 300,000 to 150,000 years ago. Dr. Arun Sonakia of the Geological Survey of India found the fossil exposed on the ground surface of a thick Quaternary sediment of fluvial origin and embedded in a fossiliferous gravel conglomerate on the north bank of the Narmada river. This is near the village of Hathnora and some 40 km northeast of Hoshangabad town. Preserved parts of the specimen are the left side of the cranial vault, most of the base of the skull, and the left half of the brow ridges and orbit. Hence, it is a *calvaria*, not a complete skull with a full face including upper and lower jaws. Teeth are absent. In 1997, an announcement was made of the finding of a hominid right clavicle from Middle Pleistocene deposits in the Hathnora region during field explorations between 1983 and 1992, a bone that Dr. A. A. Sankhyan of the Anthropological Survey of India, Calcutta, associates with the Narmada Man calvaria and describes as having belonged to a female the size of a modern adult pygmy of “stocky” build.

In Sonakia’s description, published in 1984 in the *Records of the Geological Survey of India*, he assigned

“Narmada Man” to the hominid taxon *Homo erectus narmadensis*. Its antiquity is based upon the direct association of the calvaria with stone tools, mainly handaxes and cleavers, typical of the prehistoric Acheulian technological tradition that was dominant in Middle Pleistocene times in India. The fossilized animal remains in the deposit—cattle, buffalo, elephant—include some species that are now extinct, but they are reliable “index fossils” of the late Middle Pleistocene. Radiometric dating methods are not feasible, so the age of the specimen is a relative dating estimate based upon its lithic and faunal associations.

By 1988, reexaminations of the calvaria had been undertaken independently by biological anthropologists from the Laboratory of Human Paleontology and Prehistory at Marseille in France and from the Human Biology Laboratory at Cornell University at Ithaca in the United States. The French investigator, Dr. Marie-Antoinette de Lumley, recognized that some physical features of the calvaria were not typically those found in *Homo erectus* fossils from southeast Asia, China, and Africa. For example, the cranial capacity of these Early and Middle Pleistocene specimens averages 1,000 cm³, but estimates for the Narmada cranial vault fell between 1,155 and 1,421 cm³, values within the range of anatomically archaic *Homo sapiens*. Dr. de Lumley christened Narmada Man as an “evolved *Homo erectus*.” This label is acceptable to those biological anthropologists who profess that anatomically

modern humans have a lineage that includes *Homo erectus* as an ancestral species, the anatomically archaic hominids of the Middle and Late Pleistocene (called *Homo heidelbergensis*) having an intermediate status in this evolutionary progression.

Aside from learned debates over this matter, the American investigator, Dr. Kenneth A. R. Kennedy, broadened de Lumley’s observations by an extensive examination of the calvaria using measurements, morphological analyses, and statistical procedures that support the thesis that Narmada Man (actually a young adult female) merited reassignment as an early *Homo sapiens*. The specimen was compared with crania of other hominid fossils of the Middle Pleistocene (Bodo, Kabwe, Petralona,

Dali, Ngandong, Saldanha, Sambungmachen, and those from other sites in Africa, Asia, and Europe), with which it exhibited a significant number of anatomical similarities. The archaeological data do not rule out the possibility that *Homo erectus* had inhabited the Indian subcontinent, but fossil remains of this species have not been recovered. The importance of the Narmada calvaria is that it demonstrates that the Acheulian tool tradition was practiced by early *sapiens* in a part of the world that lies between the richer hominid fossil sites in Africa and in south-east Asia and the Far East. It is the most ancient hominid fossil recovered in India at the time of this writing.

NAROLL, RAOUL (1920–1985)

Raoul Naroll was an American anthropologist whose major contribution to anthropology and other social sciences, including history, was the development of methods for conducting and evaluating comparative studies. He developed many procedures for subjecting comparative studies to rigorous analysis, and he was equally concerned with the trustworthiness of ethnographic sources. His goal was to have social scientists arrive at conclusions of theoretical and practical importance that could be trusted. The

purpose of obtaining trustworthy information—either ethnographic data or well-supported propositions—was to produce a literature that could be used to better humankind. He championed four techniques:

1. In his book *Data Quality Control*, he developed methods for the identification of control factors and bias-sensitive traits in data used in comparative or cross-cultural studies. Witchcraft attribution was one trait he found bias sensitive; it was correlated with two control factors—the length of time the ethnographer spent in the field and whether the native language was learned. Later, these two factors became the basis for constructing a sample of societies and their sources, which he felt offered trustworthy ethnographic data.

2. Naroll was concerned with Galton's Problem (i.e., whether cases in a cross-cultural study were independent) and developed five separate solutions to the problem.

3. Naroll was concerned with the nature of the culture-bearing unit in cross-cultural surveys and developed guidelines for ensuring the comparability of units.

4. He advocated the use of high-quality samples, two of which he was primarily responsible for developing—the standard ethnographic sample and the Quality Control Sample, referred to as the HRAF Probability Sample.

Many of Naroll's contributions are described in *A Handbook of Method in Cultural Anthropology*, edited with Ronald Cohen. This handbook became a major reference work. Of Naroll's substantive contributions, perhaps the most important were his studies of deterrence. He conducted both a cross-cultural study and a cross-historical study to test the theory that military preparedness prevents war. In neither study did he find support for deterrence theory. Also of importance were Naroll's studies of cultural evolution. One of his first articles was "A Preliminary Index of Social Development." In his cross-historical study of deterrence, he summarized the main currents of cultural evolution. Other studies related cultural evolution to warfare and to migration. He believed that humankind was evolving toward a world government. His next book was to review evidence on the cultural evolution of humankind. Another area in which Naroll did important research was "culture stress."

Naroll showed concern for measuring the degree of stress to which individuals, as members of cultures, are subjected. Specifically, he looked at such indicators of culture stress as drunken brawling, defiant homicide, protest suicide, and witchcraft attribution. In *The Moral Order*, alcoholism and suicide are seen as resulting from weakened moral nets.

Raoul Naroll was born in Toronto, Canada, on September 10, 1920, the only child of Tessa Soskin and Albert Naroll. He grew up in Los Angeles, California. He enlisted in the U.S. Army shortly before World War II after attending the University of California at Los Angeles (UCLA) for 3 years. In 1941, he married Frada Kaufman, and they were at Pearl Harbor on December 7. At war's end, he was an intelligence officer in Germany interviewing prisoners of war. He returned to UCLA as a junior in 1949 and continued on to obtain his PhD in history in 1953. His interests soon switched to anthropology. In 1955, he obtained a job as a research associate at the Washington office of the Human Relations Area Files (HRAF). From 1957 to 1962, he taught at California State University, Northridge, first as assistant professor (1957–1960), and then as associate professor (1960–1962). In 1962, he became an associate professor at Northwestern University, where he was promoted to professor in 1965. In 1966, he joined the faculty of the Department of Anthropology at the State University of New York at Buffalo, where he remained for the rest of his career. During this period, he and colleague Keith Otterbein developed a cross-cultural program that trained both undergraduate and graduate students. From 1967 to 1973, he served as a member of the Executive Committee of the Board of Directors of the HRAF, and from 1973 to 1981 as president. In 1979, he became a Distinguished Professor. He died June 25, 1985, of colon cancer in Buffalo, New York, age 64. Naroll's papers are at the SUNY–Buffalo archives. A selected bibliography has been published by Keith Otterbein.

NASH, JUNE C. (1927–)

June C. Nash stimulated feminist anthropology and the anthropology of work, and she has been a key figure in the study of social change within the global economy. She received her PhD from the University of Chicago in 1961 and spent most of her career at City College and the Graduate Center of the City University of New York, retiring as Distinguished Professor of Anthropology. Nash, together with her City College colleague Eleanor Leacock, and Eric Wolf, Sidney Mintz, William Roseberry, and others, developed the neo-Marxist school in anthropology that is often called “political economy.”

Nash's first book-length ethnography, *In the Eyes of the Ancestors*, examined a Maya-language peasant community in Chiapas, Mexico. Although using a now outdated and awkward behaviorist terminology, she innovatively addressed how indigenous social relations and ideologies were changing through the commercialization of crops, markets, and transportation systems, and she spoke honestly about the sometimes violent conflict that ensued. Most Mesoamerican anthropologists at this time treated indigenous communities in unrealistic ways—as changeless “cultures” or perhaps as folk traditionalists influenced by “modern” values diffused from outside—and ignored dynamics occurring both inside and outside the local social field.

Nash's next major project took her to the tin mines of the Bolivian Andes. The monumental ethnography she produced, *We Eat the Mines and the Mines Eat Us*, stimulated the slumbering field of anthropology of work. This book explores the roots of the tin miners' radicalism, including their synthesis of apparently opposite pre-Columbian and 20th-century secular Marxist idea systems; the contradictory but also tight relationship between community and workplace (being, at the same time, a relationship between women and men); and the solidarity of work groups in the demanding and dangerous work of underground mining. In addition, she recorded and edited two valuable Bolivian life histories.

Nash's Bolivian fieldwork took place amid open struggles against nationalized mining corporations, military governments, and international economic controls. Her next major ethnographic venture examined a city (Pittsfield, Massachusetts, USA) long dominated by a capitalist giant, General Electric, in the throes of deindustrialization and militarization. Although she identified political struggles in Pittsfield, the lack of resistance compared to Bolivia was striking, with a long history of corporate hegemony over local politics and culture in her view substantially responsible.

From the 1970s through the 1990s, a series of edited volumes developed Nash's key themes: social change within the global economy, artisan production, industrial work, and women's lives. Anthropology, with its romantic attraction to the exotic and apparently traditional, benefited significantly from Nash's attention to social change. In particular, her work on women (from a materialist feminist perspective) did not isolate gender as a topic, but rather examined the ideological and behavioral realities of women's subordination within the context of broader transformations.

Nash's most recent book, *Mayan Visions*, brings her back to the highland Maya country of Mexico and Guatemala. This work synthesizes the struggles of the Maya people to determine their fate in the face of powerful colonial and national political organizations and global economic relations. Nash, a superior ethnographer of local places within the world system, finishes by inquiring into the survival of plural cultures in the global community.

NATIONALISM

Our species, being a product of organic evolution, developed a complex social structure that reflects the biological structure of the human brain. The progression of this social structure is illustrated by both primate behavior and the archaeological record. Driven by biological and environmental factors, the development of culture became a decisive, and often divisive, adaptation. Within this cultural domain, primitive seeds of nationalism took forms of divisions based on shared phenotypic expressions and crude ideologies. Wealth and social status reinforced this social structure. With the development of new technologies, nationalism became more than a solidifying process; it became an aggressive political ideology based on the conceptual term of race.

The primary base of nationalism is the nation state. The concept of nation, defined as a population whose common identity creates a psychological bond and a political community, is often referred to in terms of state or country. Although nations, states, and countries may be comprised of various genetic populations, nationalism focuses on the commonality of language, ethnicity, and history. It is this nationalistic identity that promotes a psychological bond and a justified political community. This process can be seen in the philosophy of ancient Greece and the Greeks' influence on Western thought for centuries.

There are many postulated theories concerning the origin and development of the state. The writings of both Plato (c. 428–348 BCE) and Aristotle (384–322 BCE) had an important influence on the development of basic ideologies in nationalism. Essentially, the form of government is a reflection of the individual; individuals gather for the purpose of security and

have a share in the common good that would enable an individual to attain the good life. Whether it was Plato's philosopher king or Aristotle's benevolent monarch, the developmental structure and political ends were to secure domestic prosperity at the expense of the "barbaric world" around them. For example, Plato stated that the development of the stratified state, reflecting parts of the soul (for example, appetites and rationality), provided an illusionary utopia with a justified class system. Although this philosophical class system was an idealized society, the political implications were a justification of class structure of their society. In this manner, the highest form of government being aristocracy would eventually decay into timocracy, then plutocracy, democracy, and despotism. Aristotle had similar, yet different political ideas. True forms of governments that are recognized were monarchy, aristocracy, and polity, whereas the perverse forms are tyranny, oligarchy, and democracy. Acknowledging the inequality within the individual, the state would also reflect this inequality. Essentially, the state becomes an entity that enables individuals to perfect themselves and attain the good life. Ironically, the desire for equality was seen as the chief cause of revolutions and war. The basis of nationalism is to create an arena whereby these rigid social structures were maintained and protected. With the introduction of Christian theology

by the theologian Thomas Aquinas (1225–1274), nationalism incorporated the logistics of Greek philosophical thought with divine revelation (for example, divine right of kings).

Aquinas, viewing humankind's order as a reflection of a divine order, held that our species is a social species; therefore, the social hierarchy must exhibit the same qualities depicted in other social animals, but more importantly, the hierarchy that exists in the heavens. Justifying both political and ecclesiastical structure, the rule by one, whether king or pontiff, can be the only form by which a government should operate.

In this manner, religion attempted to overcome ethnicity by stressing the unity of humankind by one creator. In Aquinas's view, the king, especially a just king approved by Rome, becomes the social enforcer, just as the church becomes the spiritual enforcer, of the Kingdom of God on earth. Ironically, with each principality claiming God's sovereign charge (the Crusades), the outcome is reduced to those who have the greatest amount of holy favor. Dominions and conquest would fuel this form of nationalism during the age of imperialism.

During the age of imperialism, exploration of the known world led to the discovery of the new world. Prompted by economics and nationalism, the acquisition of new territories led to subjugation of their inhabitants and the demise of cultural aspects. At this point, one can argue that nationalism became more destructive, justifying, both scientifically and theologically, the enslavement of the "inferior" peoples of the world. In these conquered territories, or colonies, the aboriginal peoples were good enough to convert and work, yet not good enough to share in the prosperity of the empire. With the rise of imperialism, the rise of the middle class became problematic for the monarchy. The desire for equality, as Aristotle would state, led to a constitutional monarchy and representative forms of government. Problems for the church-state also arose, causing schisms and, ultimately, the

Reformation. Although philosophical attempts, such as those by Thomas Hobbes and John Locke, tried to reaffirm that the political role between a sovereign authority and subjects of the commonwealth by degree was of issue, the idea of a social contract, nationalistic pride, and newly acquired freedom turned nationalism in a new direction.

The Age of Enlightenment provided a fertile ground for new philosophical and political thought. With political unrest and civil revolutions common, economic and social stability was shaken. The expanding middle class and greater need for political freedom created the setting for acceptance of the influential writings of Jean-Jacques Rousseau (1712–1778). Acknowledging the inequalities of individuals and societies, Rousseau saw each society as developing its own political structure, via social contract, for procuring the “general will” of the society at large. Viewing society as an entity in flux, this social progression was removed from the theological domain to the social domain. Governing was moved toward a democratic form of government, whereby a just society with the common good would yield the greatest freedom for each citizen. Morality for this society would be just as independent from theology as the governing body (politics). Although nationalism would be analyzed critically and perhaps rejected, the critical inquiry and scientific revolutions continued to influence both nationalism and the developing state. With greater civil freedoms and economic independence, nationalism continued to adapt to the changing political and economic framework. However, with the discovery of the theory of evolution by Charles Darwin (1809–1882), the rise of nationalism can be evaluated within an evolutionary framework.

The greatest interpretation of social evolution was given by the British philosopher Herbert Spencer (1820–1903). Spencer, whose philosophical interpretation of social evolution incorporated the “survival of the fittest” motto, viewed society as an organism in flux. He saw societies as units that span the spectrum from simplistic to complex, with each society viewed as being in an ongoing progression from the most rudimentary form to the modern age. Society, paralleling an organism, consists of interdependent parts that function as a whole. The degree of complexity (for example, simple, compound, doubly compound, and trebly compound) was seen in terms of the degree of internal regulation and external conflict. As a society increases in complexity, as in industrial

societies, external conflicts are necessitated by changing internal regulations within societies. Stemming from this process found in industrialized societies is the outgrowth of a militant structure. Although complexity is not dependent upon the industrial/militant dichotomy, societies rarely, if ever, fit into Spencer’s categorization of society. In terms of “survival of the fittest,” rugged individualism and aristocratic classes exclude any sense of shared equality. The intensity of nationalism would act as an imputed aggregate. When applied to promote internal cohesion, conflict arising from alienation can be skillfully reduced or eliminated. The functionality of individuals and society form a cohesive unit, nationalism pitting one race against another in terms of survival.

Because of the advancements made in both anthropology and biology, our species can state with scientific certainty that we have differences only at the phenotypic level. Race, in itself, is a social construct. Yet the evolution from family to clan, tribe, city-state, nation, and empire is well documented. As depicted by James Frazer (1854–1941), cultural aspects encompass a distinctive dialect, organizations, religious beliefs, magical practices, artistic expressions, and mores/laws. Stemming from this evolutionary process, including many aspects depicted by Herbert Spencer, the evolution of sedimentary tribes from traditional hunters and gatherers gave rise to economic prosperity that stimulated trade. Nationalism, in some crude form, became a protective mechanism that spurred economic growth and regulated tribal interaction. The need for raw material and possible access to greater amounts of natural resources became both a source of conflict and a basis for internal unity.

With the advent of superior weapons and skills, dominant tribes would absorb or assimilate weaker tribes into their cultures. Because of an increased internal pressure caused by foreign influx or foreign pressure, the subordinate political system would be controlled by an influential person based on either military power or hereditary succession. This individual was given complete or near-complete authority over communal matters.

The influence of religion (magic) and mythology plays an important part in the creation of the nationalist state. Magical practices, taboos, superstitions, and rituals (sometimes based on mythology) can influence political roles and individual destinies. The crude belief in witches and sorcerers restrained or promoted a leader’s position. Eventually, theocratic

governments came to power (for example, Egypt, and Rome under Caesar). Although the relationship between religious and political domains was disrupted by the Reformation and the French Revolution, religious overtones have always remained a factor in maintaining the nationalist state.

With the rise of nations, commanding trade centers and regional resources prompted expansion and conflict with other states, such as Carthage and Rome. In the acquisition of provenances, population groups were incorporated into the mainstream cultural identity. For example, nationalism is the basis of what it meant to be Roman in the Roman Empire. Although imperialism and the Industrial Revolution would revolutionize the economic structure and create a middle class, the power structure would be transferred from one individual to a selected few. Safeguarding their country's interest is a primary issue, and the state would control access to resources. Although not necessarily a totalitarian state of existence, nationalism can bring about a state-controlled system. Re-echoing the philosophies of both Plato and Aristotle, regulation of social and economic systems is necessary for the procurement of the common good. Yet conflict, both internal and external, will never be eliminated. Corruption and incompetence are the Achilles' heel of the nationalistic state. Legitimizing the suppression of natural tendencies for the sake of the state is the hallmark of the ultimate decline of empires, as can be seen in the decline of the Roman Empire. Although far from the ideal or utopian society, the psychological manifestation of alienation is as real as the system that produced it.

As can be seen thus far, the creation of the state has certain attributes that become necessary by the state's very existence. Pressures from the environment, population, and newly created technologies make cohesion necessary for the procurement of both internal and external stability. Concepts of race, ethnicity, religion, and economic prosperity can be a source of both unity and division. Nationalism uses these concepts to create an unwavering patriotic stance. In advanced degrees of nationalism, ethics become utilitarian in nature. Unity in history and stately pride increase this sense of nationalism. Forms of alienation incurred by the individual are expected, all in the name of the state. This process can be illustrated by the conflict between Nazi and communist factions within Germany during the first half of the 20th century. The outcome of this conflict can produce one certainty; communism is the antithesis of the nationalistic state.

Recognizing the social strife caused by the Industrial Revolution, Karl Marx (1818–1883) understood the economic underpinnings of social life. Taking a holistic approach concerning social interaction, the mode of production was seen as a critical pivot for interpersonal relationships among members of a society. With the increase in technological advancements (for example, new modes of production), the stress produces alienation. This process is experienced by those individuals who partake in the segmented process of production. Production's failure to complete or provide a sense of fulfillment leads these individuals to become alienated from their work, from themselves, and from their fellow workers. When taken to the economic level, alienation and economic control produce conflict between class interests. The fundamental principles established by Adam Smith (1723–1790) were seen as part of an evolutionary-based process by which the workers will eventually rid themselves of their "false consciousness" (nationalistic tendencies) for a communal or communistic life. However, Marx failed to realize the true nature of our species. If he had taken both biology and history more seriously, including the critical analysis of his own philosophy, Marx would have come to the conclusion that communism is a utopia that can never be actualized.

In the final analysis of nationalism, it would be extremely difficult to declare any modern society free of any degree of nationalism. Whether by social contract or necessity, our species evolved into a complex social structure that had its fundamental principles rooted in our evolutionary biological past. Indeed, we are a social animal. The emergence of culture has provided our species with both the capability to populate the globe and a distinct identity. When used properly, nationalism can provide necessary psychological security and well-being for a population. This can, in fact, enrich the cultural experience as an aesthetic experience that could diffuse across territorial boundaries. However, political and economic systems rarely seek the "golden mean" when implementing policies.

Extreme forms of nationalism have caused more conflicts than any other "justified" reason. Patriotism (pride), ethnicity, religion, and economics are primary factors in stimulating greater degrees of nationalism. Stimulating the psychological euphoria created by manipulating mythological/religious fervor, justifications for atrocities become *ad absurdum*. In this

manner, marginalized and venerable individuals can fall victim to the overwhelming onslaught of the ruling class. Essentially, the greatest expressions of our humanity revert and become perverse. Examples of this process can be seen throughout history; Julius Caesar, Genghis Khan, Adolf Hitler, and Joseph Stalin all represent the zenith of unchecked power. War, greed, power, racism, and state-sanctioned criminal activity become rampant and call for a reevaluation of values.

Perhaps, to a certain degree, Plato and Aristotle were correct. Because nationalism is ingrained in our social structure, the leaders who are in control of society must have the proper aptitude and training for such a position. Although this creates philosophical questions concerning the attainment of a true democracy, the cultivation of virtues and seeking the proper mean can only serve to augment the greatest aspects of our humanity. Public and international policies governed by proper rational thought can reduce the amount of conflict, but can never eliminate its cause. Although not necessarily utopian, the degree of personal fulfillment for citizenry and peaceful resolutions for the global community are possible. Respect for sovereignty and human dignity (rights) can diffuse tensions in the global community. Furthermore, it is the duty of every nation, by which freedom and tolerance are upheld, to defend against any aggressive actions by perverse tyrants who wish to enslave members of our species. In terms of the global community, nationalism can do what biology has already done—unite our species as one species, with each expression of culture viewed as accidental rather than essential. Once and for all, the barbarians are transformed into the unexpected—a reflection of our own modern humanity.

NATIVE NORTH AMERICAN RELIGIONS

Just as there is no single American Indian “language” and “culture,” so there is no single American Indian “religion.” There once existed a diversity of Native peoples whose 2 million descendants today represent the heirs of many languages, cultures, and religious practices that still define Indian country. This world of experience included sacred ritual practices that Native peoples regarded as an essential part of secular, everyday life. Such practices were part and parcel of what it meant to be human within the varied cultures that differed from one another.

Time has altered the cultural context that sustained traditions of the past, and most contemporary Indians live very much like non-Indians. However, Native peoples still refer to a “traditional religion,” even though there was no religion, per se, that was common to all groups (nor did the word “religion” exist within the hundreds of Indian languages that were once spoken). As a field of study, Indian religion is a broad topic with a vast literature of mixed quality. It is also a contentious topic that often pits Indians against non-Indians who involve themselves in some way with the subject.

This overview focuses on religious practices that have prehistoric roots and that have continued, with modification, up to the present. It will also cite people who have been influential in the field, controversies that have arisen, and works that have been significant. The subject has drawn inquiry since anthropology's birth and will no doubt continue to do so regardless of the heated debates that periodically emerge.

Early Studies of Indian America

Students of culture evaluate all early material related to Native people, and this includes colonial accounts, government reports, military intelligence, and missionary journals. The formal study of the subject began with the Bureau of American Ethnology, a precursor of the Smithsonian Institution. Anthropology's forebears associated with the Bureau were commissioned to "salvage" tribal traditions for posterity by interviewing Native people who remembered, or still practiced, them. Frances Densmore, James Dorsey, Alice Fletcher, J. N. B. Hewitt, Francis LaFlesche, and Elsie Clews Parsons are but a few of the many pioneers who undertook early fieldwork that was later refined by Clark Wissler, Robert Lowie, Franz Boas, and their many successors.

The study of Indian religion has focused on the analysis of rituals, private revelations, dances, revitalization movements, herbal curing, vision seeking, and the biography of men and women specialists. Although traditions are often peculiar to distinctive regions or culture areas, certain themes and traditions do overlap. Unlike other world religions, Indian practice does not have clearly defined dogmas. Because latitude is given religious practitioners, differing opinions and nuanced behaviors occur within communities. This overall pattern should be kept in mind when considering what is described below.

Community, Spatiality, and Nature

Some have argued that individualism was a leit-motif of American Indian religious practice. This position was based on the continent-wide practices of fasting and vision questing, wherein one sought supernatural power. These practices assured participants that their hunting and war exploits would be successful. Achieving these goals meant that prestige and an elevated social standing would accrue to one who exhibited such questionably devout behavior that was so laden with self-interest.

Although persuasive, this argument has been challenged by those who say that all behaviors were community-based. That is, power was sought in order to be the best possible member of a village or camp. After all, a person's existence depended upon the network of kith and kin that composed the social universe. Thus, one sought to make as profound a contribution as possible to the community's continued survival.

A middle position to these contrasting approaches was suggested in the mid 20th century by the "culture and personality" school of anthropology. It detected patterns of behavior that tended to vary from one group to the next, with each group revealing a prominent trait within these patterns. Harold Driver's *The Americas on the Eve of Discovery* illustrates this approach. In the tradition of Ruth Benedict (a prominent theorist), his book describes the "self-effacing Zuni," "the self-assertive Nootka," and "proud Piegan."

Native life is also concerned with spatiality. This involves conducting rituals and orienting village configurations in a manner that makes most accessible the sacred power suffusing all creation. The camp circle, for example, reflects the Eternal, which, like the circle, has no beginning and no end. Rituals also carefully include supplication to the cardinal directions, the sky and earth, while particular places are considered sacred (and visited in time of need).

Spatiality is popularly understood as a Native sense of oneness with the environment. Romanticized, Indian appreciation for geographical sites and the creatures inhabiting them has elevated Native peoples to the status of premier ecologists. Politicized, it has elicited from critics the charge of being a ploy in the guise of religion to recover land that was fairly forfeited or fraudulently removed from Indian control.

Regardless of these perceptions, a fact of life over all culture areas has been a special appreciation for natural phenomena that Native people say are invested with supernatural power. These include everything from mountain tops to lakes, rivers, peculiarly shaped stones, feathers, or claws. Thus, people commonly claim that all creatures and all geographical features command reverence. However, historical accounts suggest that the ancestors were more selective in determining where supernatural power was most likely to reside.

Language, Culture, and Religion

The term *medicine man* has been a well-known referent used by both Indians and non-Indians in historic times, and it was derived from the French word for doctor, *le médecin*. Native practitioners were known by designations unique to their people, whereas *le médecin* referred to people whom the French saw exercising a curative role within a group. Recent history has modified this usage because one now hears a gender-neutral reference to medicine "people." This new term applies to men or women

who possess some kind of curative power *or* to anyone specializing in ceremonies (curative or not) recognized by a group as traditional.

Twentieth-century social thought and traditional Indian life uniquely merged together in transforming what anthropologists call the “menstrual taboo.” Not Native parlance, this global phenomenon existed throughout Indian America and is in evidence (among other ways) when women are kept at a distance from ceremonial participation during what some call their “moon time.” A prohibition observed uninterrupted in some areas, it has weakened or been ignored in others. Elsewhere, as part of the cultural resurgence movement, the menstrual observance has been enlivened anew, with women themselves advocating its observance.

In a Native form of feminism, the menstrual taboo is not dismissed as a product of oppressive patriarchy preventing ritual privileges to women. Rather, value is imparted to the custom. It is said that the mysterious, monthly flow of blood was a powerful event “traditionally” honored by the ancestors.

Said to be a defining mark of gender, it required a segregation that positively recognized the special birthing power of women. In their efforts to sustain or revitalize this ancient custom, participants emphasize its reverential quality. Its restrictive nature is eclipsed by recognizing the menstrual taboo as a kind of religious salute to, or recognition of, procreation’s necessary opposites. Most people, however, simply observe the custom and offer no justification other than saying “something will go wrong if we don’t do this,” “we have always done it this way,” or “it is our tradition.”

Phrases like the Algonquian language family’s “Kitchi Manitou” or the Siouan language family’s “Wakan Tanka” are references to the highest supernatural power. Commonly translated as “Great Spirit,” this reference to a Creator-being is as conventional to modern Indians as “God” is to Westerners. Parallel understandings likewise obtain, but controversy surrounds the topic.

Anthropological studies suggest that Wakan Tanka and Kitchi Manitou are associated more with animistic notions than with a monotheistic conception of deity. Such studies identify monotheism with “chiefdom” and state-level societies (as in the south-east and northwest culture areas). However, this often elicits criticism from some Indians, who charge that their tradition recognized “the same God that white

people pray to.” The counterargument is then made that ethnographic material reveals the meaning of Wakan Tanka or Kitchi Manitou to have changed over time.

Anthropologists will note that cultural continuity or change is a fact of life found universally. Just as for groups elsewhere, Native “tradition” to one era was “innovation” to an earlier period, and an example of this is evident with the Lakota word for dog (*sunka*). When the horse was introduced to this people of the Plains culture area, they needed a name for it. Because this marvelous creature carried burdens as no dog ever could, and because its speed and utility to the people were unequalled, the name that seemed most natural was *sunka-wakan* (*wakan* translated as “sacred” but implied mystery, incomprehensibility, awe, and wonder), or “sacred dog.”

Some will argue that when Wakan is associated with Tanka (“great”), the word traditionally referred to the totality of all mysterious, sacred, awe-inspiring phenomena of the supernatural world that humans beheld in wonder. Only in the historic period, it is further added, did the Lakota associate Wakan Tanka with one all-powerful Creator figure. This is extended to numerous Indian groups with comparable language equivalents, but such an understanding generates controversy among those who insist that monotheism was an age-old Native concept.

Sacred Origins

Academic theory has echoed for some time the thought of a 17th-century Jesuit missionary, José de Acosta. He proposed that Asian hunter-groups settled the Americas long ago by following animal herds. The Latter Day Saints (Mormon) founder, Joseph Smith, outlined an alternative theory in his early 18th-century *Book of Mormon*. Most Indians and non-Indians consider this an unsubstantiated connection of Native peoples with Old Testament Israelites, whereas non-Mormon Indian “fundamentalists” propose that their origin stories should be accepted at face value.

Joined even by non-Indians in this reaction against academic theory, Native people sometimes speak of North America as “turtle island,” a reference to the earth being on the back of a turtle. Some will claim that Native peoples associated the turtle’s head, legs, tail, and shell with geographical features that exist from the Arctic to the Caribbean. Although satellite photography reveals the flaws of this contemporary

“teaching,” “turtle island” does describe a type of tale found in Indian oral literature.

In a study of 300 North American creation stories, eight basic types were found to exist (and have global parallels). The “earth diver” category is widespread, but is only one of these types. It involves a Creator-figure who tells animals to dive to the bottom of the sea and bring back mud from the bottom. Generally, after three failed attempts by different creatures, the turtle (or duck, as in California) is then sent and returns with a mouthful. The Creator puts it on the creature’s back, and it spreads to become the land that will now support a human population.

The other categories of Native genesis tales are “emergence stories” (in the Southwest), which tell of a people’s coming from a lower-world, through several levels, to what is now the earth’s surface; “world parents” stories, wherein there is a sky father and earth mother (found in southern California and the Southwest); “spider-as-Creator or first-being” stories; stories that tell of the “creation or formation of the world through struggle or robbery” (along the west coast of Canada extending down to southern California); creation “arising from the corpse of a giant” (in New York and Washington); “two Creators” who are brothers or sisters competing with one another; and one type that tells of a “blind brother” creating people better than his younger sibling. These creation stories are Native America’s counterpart to those found in the holy writ of other religions.

The “Peace Pipe”

Although there are many Indian religious practices, the smoking pipe emerges as a recurrent symbol of expression. It is not the totality of Indian religion, nor is it a symbol that synthesizes the creed of any one group. It is, however, a commonly recognized instrument of ritual overarching the North American continent. Popularly referred to by non-Indians (and even some Indians) as a “peace pipe,” this religious artifact is now commonly known as a “sacred pipe.”

All of Native America made use of pipes with incised, varied designs. They were used for either religious functions or for leisure (different areas of the country maintained one emphasis or the other). Prehistoric pipe usage is evident in the numerous pipe bowls excavated from many sites throughout North America.

The early contact period in eastern Canada is best known through *The Jesuit Relations*, and they report pipe rituals and casual smoking corroborated by later accounts. The Lewis and Clark expedition regularly noted occasions at which the pipe was used, as did George Catlin after them. His name is now associated with the red pipestone (“catlinite”) common to many bowls. References in early accounts to a “calumet” are to a special kind of ritual pipe.

Woodland peoples made much use of the pipe, and one scholar asserts that the full depth of Plains Indian religion might be understood only through study of the pipe and its accompanying ritual. Meanwhile, the Southwest culture area developed ceremonies that did not rely on its use. California saw tobacco ceremonially smoked and also eaten in order to test the virtue of young women. Smoking was done in Alaska to alter consciousness and induce guiding visions.

The 20th-century pan-Indian movement drew upon pipe usage as an especially important sacred instrument of ritual. It has become somewhat of a religious thread binding the many-patterned fabric of Indian culture and religion. Such is why a rural Abenaki from Maine can meet with a reservation Shoshone from Wyoming and urban Chippewa from St. Paul and celebrate their solidarity through smoking of this unique religious artifact.

The Sweat Lodge

A practice known continent-wide in both secular and sacred spheres of activity is today generally referred to as a “sweat” or “sweat lodge” ceremony. In a small to large, igloo-shaped structure holding anywhere between 2 and 20 people, hot rocks are placed in a central pit, water is sprinkled on the rocks, and prayers are led by a medicine person, who conducts the ceremony. Both physical and spiritual strength are sought by participants, who some say re-enter the womb and exit the ceremony reborn. Aided by the interest of non-Indians, this ceremony is now practiced in urban and reservation Native settings by young and old alike, where just years earlier it had been a custom preserved by relatively few.

The Native American Church

Drug use of the 1970s led many to Indian country in search of a botanical mysticism thought to exist within the Native world. The reality that existed was

quite different. Alcohol was unknown to prehistoric Indian America other than being ceremonially employed by southwestern and Mexican tribes (even its secular use in this region was limited). Jimsonweed was ingested by an assortment of groups from California to Mesoamerica for the pleasure it induced or for more serious concerns (for example, predicting the future, curing the sick, communicating with supernatural powers). Other narcotic mushrooms, beans, leaves, and plants were part of this complex of Native religious pharmacology, but none of these attained the popularity of peyote.

This carrot-shaped root is native to the deserts of central and northern Mexico (extending into Texas). Its tip rises above the ground and is called a mescal or peyote “button.” Either this tip or the whole plant may be consumed. It also can be prepared as a spinach-like porridge, or brewed as a kind of greenish tea. Mescaline, in combination with other alkaloids contained in the plant, produces what nonpeyotists call “hallucinogenic effects.”

Sometimes simply referred to as “peyotism” or the “Peyote Road” (by members), organizations began to form after the turn of the century. After 1921, peyotism spread from state to state under the incorporated title of Native American Church. Today, peyotism is found throughout the American and Canadian plains, the Southwest (especially among the Navaho), the Southeast, the Great Lakes region, and isolated places elsewhere. Migration to cities also extended peyote influence beyond the reservation milieu. In the United States, it is associated with the Kiowa and Comanche of Oklahoma (around 1870), and from them, the Church spread rather quickly. In recent years, attempts to outlaw the use of peyote (by both the government and some tribal councils) largely have been abandoned (except among non-Indian users).

Origin stories that relate the coming of peyote vary, but all point to a belief that the supernatural took pity on Indians and decided to communicate spiritual power through a special plant—peyote. Newly subjugated groups appreciated this important gift because it included a merging of Native tradition with the Christianity that recently had been introduced. This blending was regarded as a light in the darkness of social decay. It was a providential outreach to groups feeling supernaturally abandoned.

Even though Protestant or Catholic practice took root among Indian groups, some harbored a spiritual

restlessness that yearned for greater Native expression. Word of the “Peyote Way” brought hope that herein might be the awaited revelation—the blending of Native and Christian traditions. For some, the Native American Church represented this union, and peyote missionaries were successful in spreading what some followers call an Indian version of Christianity.

The 20th-Century Revitalization of American Indian Religious Practice

The late 20th century witnessed a revitalization of Indian religion that was significantly influenced by the popularity of John Neihardt’s *Black Elk Speaks*. This book’s appeal was bolstered by the later publication of Joseph Brown’s *The Sacred Pipe* (an account of ritual practices provided by the same “holy man”). Both works revealed an “Oglala Sioux” (Lakota) elder whose religious perspective became associated with all Indian peoples. His was the story of a people disenfranchised from the pristine wilderness that was their idyllic home. Emotionally moving, his biography recounted the destruction of an entire way of life and the religious system that was its underpinning.

Since the 1960s, this man’s image determined the trajectory of writings related to American Indian religion. Referred to as the “bible of the hippie movement” and “bible of all tribes,” *Black Elk Speaks* became the wellspring of numerous works that strove to surpass its appeal. These works propelled American Indian religious practice into becoming a significant feature of broader social trends that saw many people reevaluate their worldview and way of life.

During this period, a fertile publishing career was launched for Lakota author Vine Deloria when *Custer Died For Your Sins* became a bestseller in 1969. His blistering critique of anthropologists challenged academics to reassess their relationship to the people their work tended to objectify. In 1973, he argued in *God Is Red* that Native religious practice should be appreciated for an integrity that was just as valid as larger world religions that scholars seemed to hold in higher esteem. A corrective to an academic tradition whose harvest he found both inadequate and patronizing, Deloria’s work also opened the floodgate for works of disparate quality.

A prolific writer, his *Red Earth, White Lies* later spelled out an ideology reflected in the Smithsonian’s Museum of the American Indian. He charged that anthropological analyses are highly suspect and

should be eschewed in favor of a people's myths, legends, and oral traditions. In the same vein as biblical creationists, he insisted that Indian origin stories should be understood as containing literal truths. Following Deloria's cue, the museum exhibits feature Native accounts that conflict with theories suggesting Indians somehow migrated to North America from elsewhere.

An award-winning series of television commercials also significantly affected perceptions of Native religious practice. The series featured an actor in Plains garb à la Black Elk. With a tear on his cheek, he mournfully beheld trash littering the ground. It was this iconic figure that gave impetus to a fledgling environmental movement and equated American Indian religion as more nature-friendly than the prevailing ideologies that brought blight to the land. Indian people accepted this positive stereotype and used it to help them in the courts. It was embraced by activists who lobbied for reclamation initiatives that interwove land claims with religion. Although this trend often polarized affected populations, sympathetic judicial decisions nonetheless restored Indian privileges in, or control of, lake, river, and mountain sites that were adjudged sacred to Native ancestors and their descendants.

Tribes often enlisted the testimony of anthropologists to help win favorable verdicts for cases that were showcased nationally. Varied media brought much attention to the Iroquois, who sought large swaths of land in New York; to numerous Great Lakes peoples, who fought to retain fishing rights; and to the Lakota, who pleaded for a "return" of the Black Hills to their ownership. Within these and most other legal disputes, Native groups insisted that their efforts were grounded on a religious imperative that identified them with the water, soil, or creatures that "the Creator" enjoined them to protect and with whom they identified as a people.

Besides wearing apparel and hairstyles, Native peoples also popularized neutral religious terminology that later became the vocabulary for many non-Indians. Those involved with tribal religious practice espoused a new vocabulary that substituted "spirituality" or "teachings" for the word "religion." Similarly, "God," although used, was often replaced with "Creator." The tenor of the time had given a cadence to "religion" and "god" that reminded too many people of lifeless church buildings, dry texts, and rote prayers from distant Europe.

Carlos Castaneda became a household name after publishing his bestseller *The Teachings of Don Juan*. Deloria chastised scholars who mixed with Native peoples, but Castaneda presented himself as academe's preferred alternative. He claimed to be an anthropologist who lived with the Yaqui people and who learned about their universe from the inside. His books became popular, and Castaneda's life was the cover story for *Time* magazine (March 5, 1973).

Don Juan was a biography that vied with Black Elk material as an inspirational tome of the times for college students. Its several epistle-like spin-offs were used for courses and discussion groups within academic circles. The contention of this literature was that Native peoples preserved a knowledge of drug use that Western peoples would do well to learn. After wielding much influence outside the Indian world (and revitalizing religious interest within it), Castaneda received scrutiny by scholars who called into question the entire corpus he claimed to discover while living with Yaqui religious practitioners.

Castaneda won fame, but an abiding pall hangs over his work because most people, years after the fact, regard it as fiction. Nonetheless, his efforts engendered interest and fascination with Indian religious experience. They spawned literature by and about American Indian religion that now inhabits bookstores and that challenges readers to discern authenticity.

At these bookstores, one finds studies of religion and culture interspersed with volumes that cast popular appeal and sometimes fraudulent representations of Native practice and thought. As a result, consumers made a bestseller of Forrest Carter's *The Education of Little Tree*, and speakers regularly quoted "Chief Seattle's speech" when addressing the sacredness of the environment. Relatively few were aware that both works were written by non-Indian authors.

Lame Deer, Seeker of Visions, the popular biography of a contemporary Lakota medicine man, was anti-establishment in tone and fostered a widespread impression that "real" Indians could not also be Christian. Other works echoed this sentiment, which had been stated by Deloria in angrily direct terms. He distilled an opinion that was frequently heard within the pedagogy of Indian activists: "Christianity has been the curse of all cultures into which it has intruded." Religious attitudes and literature that began to pervade the Indian world were a counterpoint to

the reemergence of Christian fundamentalism in mainstream America.

The biography of *Rolling Thunder*, spiritual guide to a music group known as “The Grateful Dead,” won admirers within the band’s cult following and many others within the Woodstock generation. Life stories of other medicine people also were numerous over the decades, but the biographies of Lame Deer, Rolling Thunder, and Wallace Black Elk exercised the most influence. Having a marketable name but no biological or theological connection to the holy man of Neihardt and Brown, Wallace was candid in his condemnation of Christian churches within Native communities. He and others evangelized this position by addressing audiences via the lecture circuit.

As the new millennium dawned, so did the hope for new life in Indian America. The casino industry was transforming the economic status of different tribal communities, and religious practitioners were revitalizing traditions that had been suppressed, forgotten, or abandoned. At the same time, television, films, and a broad array of Indian and non-Indian writers fostered a conventional wisdom that Christian affiliation was forced upon ancestors who wanted no part of the new religion.

It was widely assumed that had they been given a free choice, elders would have retained their age-old practices and would not have joined the various Christian denominations that were now found throughout Indian America. By restoring the old practices, their descendants could amend the horrific history wrought by culture contact. Contrasting with a prevailing opinion that had been present since 1492, non-Indian commentators accorded an understandable, sometimes effusive, compensatory respect for Native religious practices.

A century earlier, Christian missionaries sought to replace Native religious practices with those of their own denomination. By 2000, many Christian ministers were assisting Native peoples to derive spiritual succor from tribal religious traditions that even the ministers regarded as having merit. Sectarianism had fallen into disfavor, and ecumenism had become commonplace.

Black Elk Speaks and *The Sacred Pipe* had been in the forefront of Indian cultural resurgence. They also inspired many Indians and non-Indians to appreciate Native religion anew. People saw in Black Elk a vision of the sacred that was compelling. However, the holy man’s fuller tale had not been told, and by century’s

end, it generated a new debate. *Black Elk: Holy Man of the Oglala* revealed in detail that the sainted patriarch of traditional religion had been a devout Catholic for most of his life.

He was best remembered by those who knew him as an elder who lived the Christian faith along with many from his era. Brown admitted that he and Neihardt avoided this topic because they thought their readership would see Christianity as compromising the holy man’s “Indian-ness.” As a result, their portrayal of Black Elk as a resolute traditionalist made him a beacon for nativists. It moved them to seek religious meaning within Indian practice alone and forsake whatever Christian affiliation they might have had. This position was dramatically advanced by the American Indian Movement (AIM) in many highly publicized national protests, such as the occupations of Alcatraz, Wounded Knee, and the Bureau of Indian Affairs offices in Washington, DC. Activists spearheaded protests that included the restoration of Indian religious practices they understood to be traditional.

In his autobiography *Where White Men Fear to Tread*, Russell Means (a Lakota) stated that one of AIM’s concerns was to help restore the religion of people such as the revered Black Elk (Means was unaware of his Christian participation). Because AIM’s religious spokesman was Wallace Black Elk, it was only natural for Indians and non-Indians alike to conclude that Wallace was kin to the senior holy man, and that AIM’s and Wallace’s religious disposition was the same as the elder Black Elk’s. By the end of the 20th century, this understanding was as much widespread as it was inaccurate.

Urban Indian and non-Indian academics and activists were at the forefront of a revitalization movement that still unfolds within the Native world. Although the stridency has abated, Christian missionaries are still charged with complicity in bringing about the “End of the Trail” for Indian populations. However, church-going Indians still hear that the only redemption they need is redemption from those who brought Christianity.

Many were not aware that the medicine men, as custodians of tribal religious traditions, formerly claimed membership in some Christian denomination. Others tried to exorcise institutional Christian presence from among their people. This latter group asserted itself in the late 20th century where earlier, an individual might be known as a Catholic, Protestant,

or Peyotist medicine man (as revealed in the biography of the much-respected religious leader, Fools Crow).

Although it was a popular tenet that Indian Christianity was oxymoronic, many Indian people continued their denominational affiliation. They also affirmed the interest in Native tradition that many younger people were expressing. If the next generation could find new life by such means, elders gladly bestowed their blessing. They did so not because they thought the young should forsake Christian practice, but because the gospel itself affirmed teachings that proffered faith and hope. Such virtues were sorely needed among so many Native peoples who were locked in the grip of a haunting poverty.

Sometimes accompanying the revivalism preached by nativists was what one anthropologist has termed “ethno-gnosticism.” That is, many began to assert that Indian peoples should have proprietary rights to the knowledge and conduct of rituals traditionally associated with tribal religions. This sentiment sought to have Native people alone speak on matters pertaining to the Indian world. Such exclusivity was prompted by some Indians and non-Indians who were selling their real or purported expertise to anyone who paid for their services.

This nativist position bred difficulties of its own. Anthropologist Sam Gill, teaching at the same university as Vine Deloria, was as outspoken as his colleague when he wrote that Indian hegemony within the public arena had itself become a problem. His argument is shared by others and has stirred debate, but scholars rise above it and still render a faithful reflection of Native practice. Noteworthy Indian anthropologists and their work include Alphonso Ortiz’s *The Tewa World* and Robert Hall’s *An Archaeology of the Soul*.

Native North America is composed of diverse people who devoutly attend their Christian church, participate in some tribal religious tradition, or do both (atheistic thought is seldom heard within Indian country). As they go about their daily routine, most Indians are not involved with scholarly discussions and the public activism featured on newscasts. Rather, they conduct an everyday life that is filled with the same mundane activity common to non-Indians. It helps them continue to live with a vision of the sacred that family and tribal tradition have always insisted is necessary to possess.

NATIVE PEOPLES OF CENTRAL AND SOUTH AMERICA

The study of native peoples of Central and South America addresses many scientific and humanistic debates. It is a subject of considerable intrigue for archaeologists, linguists, and cultural anthropologists. Who are these people? Are they exotic others who engage in hallucinogenic drug use and shamanistic healing? Are they remnants of lost empires, victims of Western civilization’s aggressive quest for gold, Christian souls, and subjects for the medieval crowns of Europe? Are they romantic rebels who fight to preserve simple lifestyles in the remote jungles of Latin America? Or are they the blessed poor of the earth, crying for justice? How do we discover their true identities, unmask the myths and mysteries that surround them, sort out the lies and the truths of their histories, and learn how their lives reveal the broader issues concerned with the future and fate of the Western hemisphere?

At the time of the European invasion of Central and South America, it is estimated that between 15 million and 50 million people inhabited the diverse geographic region that stretched 7,000 miles between the

Rio Grande River and Cape Horn. Archaeologists continue to find new evidence to explain how and when they came in various waves from several areas of Asia between 20,000 and 40,000 years ago. As many as 2,000 different languages were spoken among the peoples, whose cultures varied according to their adaptations to a wide range of environments, including rain forests, desert coastal areas, mountains, fertile plains, and marshes. In the 21st century, their numbers are still difficult to discern, but for another reason. Latin America is a land of the *mestizo*, persons of mixed native and European heritages. Despite the fact that most Latin Americans have indigenous roots and many native peoples are assimilated in part into mainstream lifestyles, native peoples can still be identified by distinctive language and cultural practices. They sustain diverse authentic identities in traditional communities, many of them in isolated regions of Central and South America.

Native peoples of Central and South America, referred to as “indigenous,” or “Amerindian,” can be studied in terms of their historical adaptations to their environments in specific culture areas. In his classic outline of South American cultures, George Peter Murdock defined the following areas: Isthmian, Caribbean, Colombian, Peruvian, Chilean, Fuegian, Pampean, Chaco, Paraguayan, Eastern Lowland, Atlantic, Goyaz, Para, Xingu, Bolivian, Montana, Jurau-Purus, Amazon, Loreto, Caqueta, Savanna, Guiana, Orinoco, Coastal Caribbean, and Floridian. Murdock’s culture areas are characterized by linguistic affiliation, food production techniques, crafts, housing types, community organization, and marriage and kinship norms. Peoples within culture areas share religious ideas and knowledge of the environment or practical skills with each other. Their languages typically share mutually intelligible terminology and grammatical structures. Through trade, they share resources. This can but does not necessarily lead to more complex social organization. Culture area studies are primarily ecological in their focus. They are also the focus of linguistic studies.

Native peoples of Central and South America can also be studied in terms of the development of levels of complexity in their social and political systems. While many culture areas remained sparsely populated, the availability of resources, the development of agriculture, and increased trade allowed some populations to grow denser. Peoples like the Aztec, Maya, and Inca developed complex political systems,

elaborate ritual centers, and impressive civilizations. They also expanded their territories through warfare and were known to practice human sacrifice of their prisoners. Archaeologists continue to discover evidence of a broad range of human sacrifice practices throughout Central and South America, including voluntary sacrifice of children in some areas.

The study of native peoples of Central and South America also examines how these societies changed over time and how they either collapsed or were destroyed by European invasions. Archaeologists, linguists, and cultural anthropologists uncover evidence to understand the role of ancient native cultures in past developments and present realities. Contemporary Latin American nations are proud of their indigenous roots and support research that recognizes the wisdom of native peoples and their accomplishments. Museums throughout Central and South America display impressive artifacts of gold, jade, and other precious metals as well as pottery, stone sculptures, codices and khipus. Vast architectural ruins, remains of Maya and Inca glory, attract large numbers of tourists to Mexico, Guatemala, and Peru each year.

Native peoples of Central and South America can also be studied as small groups of survivors in remote regions, living in simple relationships to their environments, but certainly not isolated, unchanged, or in peace. These groups face uncertain futures as modern governments typically seek to exploit their natural resource endowments for financial gain. Forests for hardwood, gardens, and small farms that grow food for plantations that produce cash crops, mountains for minerals, and displacement of natives for cheap labor are part of a common policy among all nations of Central and South America. Cultural anthropologists tell the stories of these struggling peoples in diverse environments, published as ethnographies.

Cultural anthropologists also study native peoples of Central and South America in terms of how they adapt to the modern world and assimilate into the multicultural societies of Latin America. They tell the story of native tragedies and triumphs. Native peoples suffer the highest rates of mortality. They are the poorest and the least educated. They are excluded from political processes and suffer the greatest human rights violations. Increasingly, however, many have become successful political leaders in their respective nations, challenging the systems that exclude and oppress them. Others have high-profile international identities as champions of human

rights and environmental justice. And many others work to preserve the dignity of their lives and cultures at local levels through cooperatives that sponsor education, health care, housing, and economic development from the grass roots. Anthropologists work to preserve their languages and cultural knowledge, particularly of their natural environments.

A large number of charitable organizations throughout the world send volunteers and resources to assist native peoples. A growing number of democracies in Latin America are beginning to recognize the importance of native peoples and are including them in democratic processes; however, this is both long overdue and largely unrealized for most native peoples. Native peoples contribute to the economies of Latin American nations through their labors in agriculture, fishing, and mining. They also contribute greatly to the culture of their nations through their costumes, food ways, music, dances, religious beliefs, crafts, and festivals.

NATIVE PEOPLES OF THE GREAT PLAINS

Native Americans of the Great Plains are an important part of popular culture. They have been represented in anthropological studies, literary works, and the cinema. Many of these representations focus on nomadic communities engaged in hunting bison, military activities, and religious practices alien to many citizens of the United States. Although the vast majority of these perceptions date from the expansion of the settlers

from the United States into the region, the occupation of the Great Plains by many indigenous peoples predate the presence of colonial nations.

Early Occupations of the Great Plains

According to archeologists, people began occupying the Plains by at least the Clovis Period, 14,000 years ago. Artifacts associated with these widely dispersed sites suggest that these hunting and gathering populations stalked various types of mega fauna and gathered locally available plants. Sophisticated bifacial tools made of fine-grained lithic material were used to dispatch mega fauna.

As climatic conditions became dryer, temperatures increased, grasslands expanded, and once flourishing streams transformed into marshy areas and small lakes. These environmental changes aided the range expansion and herd size of bison. Predictably, indigenous populations began to focus on ungulates. Innovative hunting techniques led to the ability to mass harvest bison. Corrals and cliff jumps began to appear in the archeological record. In addition, a number of archeological sites evidenced the successful storage of perishable meats over a long period.

Around 2,000 years ago, pottery and evidence for small-scale farming began to appear along rivers in the eastern Plains. Some of the domesticates grown included corn, beans, squash, sunflowers, and tobacco. As time went on, many more varieties of corn and beans were developed. It is estimated that the Arikiras, residing along the Upper Missouri River, grew 18 varieties of corn and 10 types of beans. The Arikiras are a Caddoan-speaking population that represent the northernmost migration of Caddoan-speaking communities that had originated in eastern Texas.

Migrations of Indigenous Peoples Into the Great Plains

As Caddoan-speaking populations, such as the Arikiras and the Pawnees, migrated into more northern portions of the Great Plains, small communities of Apaches also began to make their first entrance into the region. Around the 1700s, however, numerous Native communities began to migrate into the region. Two events accelerated these later migrations: the impact of colonial expansion further east and the ability to mass harvest bison through the use of firearms and horses. This was the period in which the Lakotas, Omahas, Poncas, Osages, Comanches,

Kiowas, Cheyennes, Arapahos, Otos, Missourias, and Quapaws entered the region.

Expansion of Colonial Nations Into the Great Plains

Colonial nations accelerated their expansion into the Great Plains after the 1700s as well. In the Southern Plains, Spanish, French, British, and, later, American entrepreneurs, administrators, and in some cases, missionaries moved into the area. The immigration of these peoples as well as substantial numbers of nomadic populations disrupted earlier trade networks, subsistence schedules, and ultimately the availability of key resources, such as bison.

Transport routes developed along major rivers in order to ease the passage of settlers moving farther west, the ability traders expanding their sphere of influence west, and the provisioning of these new markets. Traffic along the Arkansas, Platte, Missouri, and Red Rivers contributed to the spread of devastating diseases. By the late 1700s, smallpox, measles, typhoid, cholera, diphtheria, and flu were causing demographic havoc among indigenous communities. In general, the elderly and the very young succumbed to these diseases in greater numbers than the rest of the population.

Colonial Expansion and Indigenous Resistance

Colonial nations frequently used Native communities as auxiliary troops in their wars against hostile colonial competitors and indigenous nations. With the use of firearms and horses, warfare became more deadly than in the past. As the United States secured its position in the region through military actions, Native peoples lost their status as allies and, like hostile communities, became a policy problem for the expansionary plans of the states. Consequently, total conquest of Native populations became the goal of the United States. Strategies implemented to succeed in this goal included land dispossession and a

growing array of assimilatory practices. These latter aims included forced changes in religious practices; social structures, such as governmental organizations; educational methods; language use; subsistence practices; the function of kinship; the mode of dress; and even the architectural style of houses.

Government administrators implemented three policies to succeed in their assimilatory policies. These included the establishment of reservations, the creation of boarding schools, and the allotment of tribally owned land. Through the use of civilian reservation administrators, often backed by military units, practitioners of indigenous lifestyles encountered punitive consequences. Students attending boarding schools faced difficulties understanding this American style of learning. Not knowing their languages, history, religious traditions, or often the basic aspects of their cultures, the students experienced further alienation upon returning to the reservations.

Fighting for Change Through the Court Systems

Although tribal lands were no longer allotted after 1934, issues concerning the seizure of lands for the extraction of minerals and oil continue to plague contemporary communities. Unfair leases negotiated by the Bureau of Indian Affairs to extract these resources are now under the oversight of tribal governments. A number of communities, such as the Pawnees, Lakotas, and Comanches, have taken cases

to the Indian Claims Court in order to have illegally taken land returned or to receive monetary compensation for the loss of this land.

Current Issues Facing Native Peoples of the Great Plains

Because of recent federal policies, tribal governments have begun to regain some of the sovereignty they had lost in the past. Unlike in the past, these governments can now contract their own leases to corporations, administer their own schools, engage in indigenous religious practices, and attempt when necessary to regain the use of their own languages. Numerous contentious battles continue, however. These center on the ability to run casinos, protect sacred sites located on public or private lands, increase economic development on the reservations, and receive the monies obligated to them because of provisions in past treaties.

The Role of Anthropologists Among Great Plains Societies

During the reservation era, numerous anthropological studies occurred among inhabitants of these agencies. Much of this early work focused on oral histories concerning the pre-reservation era. Because most of these early fieldworkers were employed by museums, they also collected numerous culturally important artifacts. After the passage of the Native American Graves Protection Act in 1990, many of these culturally significant items were returned.

Currently, many anthropologists working in the Great Plains engage in ethnohistorical research and/or applied work. One area in which many anthropologists have been involved is the issue of sacred sites. Because these sites are often located on public and private lands, little effort is made to protect them. Native leaders and anthropologists have collaborated in a number of cases in order to keep these sites whole.

Other anthropologists have worked hard to dispel some of the popular myths of Native American lifestyles during the 1800s. Through this work, it is hoped that future movies, popular books of literature, and general stereotypes of Native peoples can be reassessed.

NATIVE PEOPLES OF THE UNITED STATES

Currently, the United States has 562 federally recognized Native American communities and more than 270 reservations. Reservations range in size from the largest, inhabited by the Navajos in New Mexico and containing approximately 16 million acres, to fewer than 10 acres, as is the case for various Native communities in states across the United States. Populations today are beginning to equal those that existed at the time of contact. Most demographers assume that the United States supported 5 to 8 million people prior to the spread of newly introduced diseases. Diseases such as smallpox, measles, influenza, bubonic plague, diphtheria, cholera, and typhoid spread with the advance of contact. Some of these diseases occurred in waves and frequently disrupted subsistence cycles, the transmission of knowledge between generations, and the ability of communities to remain viable polities.

In some cases, epidemics eliminated entire communities, and in others, it resulted in the death of 85% or more of the population. Generally, these epidemics killed the young and the elderly in disproportionate numbers. This resulted in the loss of numerous categories of knowledge retained by the elderly. These new diseases definitely accelerated the region's depopulation and probably contributed to the inability of indigenous communities to resist the continual encroachments of colonial nations.

Because of patterns of Euro-American colonization and the disappearance or relocation of indigenous

communities caused by newly introduced diseases, most Native peoples currently reside west of the Mississippi River in the states of Oklahoma, California, and New Mexico.

Ever since colonists arrived in the United States, researchers have been interested in the origins, political economies, kinship structures, and religious beliefs of Native peoples. As anthropology emerged as an academic discipline, knowledge about these areas became more systemized and contributed to both the development of federal policies as well as paradigms associated with cultural, archeological, and linguistic anthropology.

Bureau of American Ethnology

The development of the Bureau of Ethnology in 1879 accelerated these areas of study. Throughout the reservation era, anthropologists, often working in concert with museum or other collecting agencies, began to participate in ethnographic and archeological studies of Native communities across the United States. Information about aspects of kinship, warfare, religious ceremonies, social structures, political organizations, economic activities, and a wealth of other details was obtained from numerous indigenous communities in the United States. Much of the information collected led to the development of central theories in anthropology. For example, work with the Shoshones in the Great Basin permitted Julian Steward to develop his evolutionary scheme of political societies and to contribute a lexicon critical to anthropological discourse.

With the help of Elias Parker, a member of the Iroquoian nation, Henry Morgan illustrated the diversity of kinship systems among Native populations. Building on his work, future anthropologists contributed to the study of the various functions of kinship.

Scholars such as Harrington, Worf, and Powell focused their efforts on the linguistic diversity within Native North America. Through their efforts, language families became systematized. Noting the rapid disappearance of Native American languages, these scholars attempted to record as many of these languages as possible. Although only 150 of the approximately 8,000 languages spoken at contact are currently used in the United States, most current linguists estimate that as few as 10 indigenous languages will remain viable in 2050.

The Beginning of Applied Anthropology

Speculations concerning the origin of Native Americans have riveted scholars since the time of contact. Prior to the 1800s, whether viewed as remnants of the Lost Tribe of Israel or survivors of Atlantis, many researchers believed indigenous occupants of North America had degenerated from some ideal Caucasian past. Continental thinkers correlated this degeneration with environmental factors. Recognizing the implications of this philosophy for the future of the recently arrived colonial inhabitants to North America, local scholars searched for alternative explanations to account for phenotypic differences between indigenous and colonial peoples.

As an outgrowth of this conundrum, by the 1800s, ethnological research emerged as a method to study and systematize information about Native Americans. During this early anthropological era, researchers inverted European explanations of change by attributing human diversity to societal progression rather than to externally induced factors affecting the mental capacities of individuals.

With this shift in paradigms, American scholars speculated that societies progress from savagery to civilization. Whereas these early ethnological perspectives caused a shift from a paradigm of degeneration to one of progression, the early evolutionary model assumed a predictable evolutionary trajectory. Many researchers assumed that social engineering could accelerate the transition from “savagery” to “civilization.” For example, reindeer herding was taught to Arctic populations in order to transform these hunting populations into pastoralists. Farming was instituted among nomadic communities in the Great Plains in order to change these societies into sedentary agricultural communities.

Although these evolutionary perspectives colored the kinship studies of Henry Lewis Morgan, the biological research of Samuel G. Morton, and the historical research of Henry Rowe Schoolcraft, each of these works contributed to a greater understanding of social complexity among indigenous peoples. Their work also opened the door to a more scientific study of the peopling of North America.

Origins of Native Peoples

Like many other human societies, Native peoples understood their origins through religious teachings.

In some cases, Native peoples emerged from the earth, were created from mud by powerful gods, or were transformed into humans from another form. Even with these variant viewpoints, indigenous religious beliefs emphasize that Native peoples originated in North America.

Through the use of scientific methods to gain a better understanding of the origins of Native peoples, anthropologists lack the paradigms to account for these faith-based beliefs. Instead, their inquiries rely on archeological, linguistic, and biological data to determine the timing of indigenous migrations into North America and the location of the original homeland of these populations.

Archeological Evidence of Native American Origins

Among archeologists, there are two major theories employed to account for the presence of Native peoples in North America. The most common theory presumes that Native peoples migrated into North America sometime after 18,000 years ago. In this scenario, small indigenous populations walked across Beringia, a land bridge that spans across the Bering Strait during ice ages. As glaciers advance, shallow seas, such as the Bering Strait, become bridges between land masses. According to this theory, small communities migrated from Asia into North America.

A second theory assumes that indigenous communities used boats to travel from Asia to the North American continent. Although no evidence of watercraft dating to 18,000 years ago have been found in the Americas, this theory provides an explanation of early sites located in South America.

Debates rage over the timing of these migrations into North America. The first agreed-upon occupation of the continent is a sparsely populated group referred to as the Clovis. Clovis sites appear suddenly in widely dispersed parts of the United States and northern Mexico. Issues arise over whether any archeological sites predate those associated with the Clovis. Potential pre-Clovis sites include San Diego Complex, Old Crow Flats, Orogrande Cave, Pedra Furada, Pikimackay Cave, Monte Verde, Chesrow Site, and Fort Rock Cave.

Linguistic Evidence of Native American Origins

Linguistic evidence of the peopling of North America suggests three main migrations into the continent.

Using stable categories of words, such as body parts, base numbers, and pronouns, lists of indigenous words associated with these stable categories have been compiled. Based on this effort, three clusters of languages were identified; the Amerind, Na Dene, and Eskaleut. According to the study's conclusions, Amerind speakers entered the continent around 9000 BC, Na Dene languages about 7000 BC, and Eskaleut by 2000 BC.

Biological Evidence of the Peopling of North America

A number of researchers have explored skeletal structures, dental morphology, and, to a lesser extent, genetic information in order to determine both the origin and the timing of migrations into North America. Based on this work, most scholars assume indigenous peoples migrated into this continent from Siberia as early as 12,000 years ago. A smaller contingent of researchers suggests that numerous migrations into North America occurred and originated from places other than Siberia. Possible homelands have been identified in the Causcoids, Japan, and China.

Earliest Agreed-Upon Indigenous Occupants of North America

About 12,000 years ago, the PaleoIndian Tradition began. This period included a series of temporally separated big game hunting groups. At the beginning of this era, numerous small sites exhibiting similar technologies appeared in the United States. Referred to as the Clovis Period, these sites encompassed a sophisticated bifacial tool technology. In addition, excellent lithic materials were used to manufacture Clovis tools. Because of issues of preservation, little is known about other aspects of their material culture. Archeologists believe that Clovis peoples hunted big game animals, many of which are now extinct. According to Martin's Overkill Hypothesis, overhunting by Clovis drove many of these mega fauna to extinction. This view is currently in dispute.

Approximately 1,000 years after Clovis, the Folsom Period arose. Like Clovis, Folsom peoples created excellent bifacial tools made from exquisite lithic materials. Folsom populations developed sophisticated mass harvesting techniques for capturing bison. These included corrals, as illustrated by the Jones Miller Site, and cliff jumps, as shown at Blackwater Draw. During this era, evidence of storage occurs as well.

The last population to be included in the PaleoIndian Tradition is the Plano peoples. As with the Folsom before them, Plano populations mass harvested bison. Because of the lack of preservation, little is known about their homes, their use of plants, and the manufacturing of items not made of stone.

After the PaleoIndian Period, the Archaic Period arose. During the Archaic Period, numerous changes took place. These included dramatic increases in the number of sites located in the United States, population increases, greater diversity of tool types and subsistence practices, the emergence of long distance trade networks, more complex human burials, and ultimately the development of social inequalities.

In the Archaic Period, populations engaged in broad-spectrum subsistence. They gathered and hunted for seasonally available resources. Critical resources included small game, tubers, seed plants, nuts, and other locally available foods.

The Archaic Period ended with the emergence of domesticated plant production. There were three centers of initial domestication in the United States. These included the Southwest, eastern Great Plains, and northeastern United States. In the Southwest, maize, beans, and squash diffused from central Mexico and began to be grown by southwestern communities by 1500 BC. Although this was an arid region, the presence of a high water table permitted the development of sustainable plant production.

In the eastern Great Plains, incipient farming of maize, beans, and squash first emerged around 500 BC. In this region, however, bison always supplemented these horticultural activities.

In the eastern United States, maize, beans, and a variety of seed plants began to be domesticated approximately 1000 BC. Throughout this region, the practice of swidden agriculture occurred. This extensive type of farming seems to have led to the presence of endemic warfare prior to contact.

Elsewhere in the United States, communities continued to participate in broad-spectrum subsistence by specializing in seasonally available resources. In the Great Plains, this subsistence strategy continued until forced into farming during the reservation era.

Historical Relations Between Native Peoples and the United States

Colonial policies initially focused on trading relations and the development of alliances with Native peoples.

Until the 1830s, Native peoples played a pivotal role in the securing of furs for overseas markets. Because of the competing interest of colonial powers in North America, indigenous nations often acted as auxiliary armies for the colonial nation with which they were allied. Once America dispatched weaker colonial states and secured its position as the sole colonial state in the United States, the importance of Native peoples to geopolitical events began to decline.

This change transformed the political relationship between heretofore sovereign tribal nations and the federal government. Suddenly, these tribal nations became conquered populations that only retained sovereignty not taken by the federal government. In order to legally institute these shifting political realities, the U.S. Supreme Court declared Native tribes dependent nations similar to a guardian-ward relationship. In this new administrative role, the federal government placed tribal communities under the aegis of the Bureau of Indian Affairs, an agency within the Department of the Interior. As a result of this policy change, the United States became legally obligated to protect and develop indigenous resources and to provide economic and social programs to raise the standard of living of Native peoples to a level comparable with the rest of society.

Through treaties, executive orders, and congressional legislation, however, indigenous communities have experienced the erosion of political, economic, religious, legal, and social sovereignty. In addition, they have been forced to transfer vast amounts of mineral, land, and cultural wealth to the dominant society.

Reservations arose as aboriginal title over territory was extinguished. With the development of reservations, Native peoples lost the right to travel freely and expand their land base beyond reservation boundaries. With little say over the organization of reservations, Native peoples were forced to accept the rules of Indian agents and mandates passed by the Bureau of Indian Affairs.

Prior to the establishment of the Allotment Act in 1887, the tribe controlled the dispensation of Native lands. This led to numerous legal and illegal sales of lands to settlers and speculators. A number of anthropologists, Native leaders, and interested citizens believed that if individuals owned their own land, they could more easily maintain control over it.

As a result, the 1887 Allotment Act was passed. The census taken of all Native peoples living on reservations was used to parcel blocks of land to indigenous

peoples. This act failed to account for the needs of future generations, nor did it provide equal amounts of land to each Native person. Instead, the largest blocks of land went to heads of households, smaller ones to the spouse, and the smallest amounts to minors. Allotments ranging in size from 80 to 160 acres were passed down to heirs and, in some cases, sold to non-Natives. Land not allotted was sold to non-Native peoples on a first-come basis. Tribal governments had no control over who would buy the surplus lands. Instead, acreages were sold to the first buyers able to pay the below-market prices.

Between 1887 and 1934, when allotment ended, Native land ownership fell from 138 million acres to 55 million acres. Because of the methods used to dispose of surplus lands, non-Natives often surpass Native populations on reservations. Even so, however, more enrolled Native peoples live on rather than off the reservations. This is the case even though unemployment is more than 50% on many reservations; housing, when available, is often substandard; schools are often dilapidated; and health problems abound. For example, on the reservations, lifespans are the shortest and mortality rates for newborns are the highest in the country.

Because of the small size of allotments and the fact that current allotments may have numerous owners because of laws of inheritance, it is difficult for Native peoples to work their land. Until recently, the Bureau of Indian Affairs leased allotments for farming, ranching, or extracting resources at below-market prices to non-Native businesspeople or corporations. The Bureau's slipshod record keeping resulted in the nonpayment of monies owed allotment owners. This has led owners of leased allotments to file a class action suit against the Department of the Interior and the Bureau of Indian Affairs. Although filed more than a decade ago, this case is still winding through the court system with no final solution in sight.

The Indian Reorganization Act

In 1934, the Indian Reorganization Act was passed to remedy some of the past abuses. With this act, monies were provided for economic development and the establishment of an apprenticeship program to maintain artistic traditions. In addition, the parceling of land into allotments came to a stop, and democratic forms of government were instituted for most federally recognized tribes.

Although allotments no longer occur, land is still taken from tribes for the development of roads, dams, and other types of infrastructure viewed as necessary by the federal government. Monies provided for economic development are given to the tribe, but no incentives are given to attract outside investors. As a result, economic enterprises not funded by tribal governments are a rarity on reservations. Because the federal government woefully underfunds apprenticeship programs for the transmission of artistic styles, few tribes are able to participate in them.

Tribal governments organized on democratic principles have also faced their share of problems. Generally, tribes elect members to the tribal council. These councils regulate tribal membership and economic development, provide for public welfare and safety, and have the limited right to maintain justice.

Membership

Although the U.S. census permits individuals to self-identify their ethnicity, tribal governments maintain sovereignty over their own membership. Enrollment in a tribe is determined in a variety of ways, the most common of which is through blood quantum. These can vary from one half to one sixty-fourth. Some Native communities determine membership through descent. This can be matrilineal, patrilineal, or bilineal descent. In other cases, individuals must show descent from a specific person on the Dawes Rolls. These rolls were developed prior to allotment in the 1880s.

The Erosion of Tribal Control Over Criminal Behavior

Since the late 1800s, the United States has given the federal government greater control over criminal activities on the reservations. Beginning with the passage of the Major Crimes Act in the 1880s, tribes have experienced continual erosion over their criminal justice programs. At this point, the federal courts maintain jurisdiction over murder, rape, assault with a weapon, and a variety of other violent crimes. In some cases, states are also beginning to take over aspects of tribal justice. Most recently, they have taken control over the management of wildlife on reservations.

Land Claims and Sacred Sites

Congress established the Indian Claims Commission in 1946 to redress the loss of Native territory. From the start, the courts decided, except in a handful of rare cases, to award money rather than the return of land titles to Native claimants. This has resulted in numerous disappointments among Native litigants. For example, the Lakotas refuse to accept monies awarded them for the illegal loss of the Black Hills. Hopis have also decided to forgo monies for land illegally seized from the tribe.

Results have not been much better for the protection of sacred sites on public and private lands. The uses of areas of sacred geography vary according to the meanings attributed to them. Consequently, some may provide a physical expression of sacred events; others may contribute to the efficacy of ceremonies or act as a portal to spiritual power; and in some cases, a place is sacred because of its relationship to the ancestors or spirits in general. Complicating the issue further is the fact that a number of Native communities may express different beliefs and practices about the same sacred area.

Throughout the United States, various geographical places are perceived as sacred by Native peoples. In some cases, these are sites for religious ceremonies and spiritual renewal. In others, however, the landscape's presence is all that is needed to retain its sacredness.

Because many of these sites are not on Native land, nor do they have any objective proof of their importance beyond the land itself, it has been difficult for Native peoples to protect how these spaces are used. Currently, 44 sites sacred to Native Americans are in danger of being destroyed. In most of these cases, resources located at or near these places are considered important to the nation's economy. For example, water from a sacred lake is needed to process coal in the Hopi area. In Montana, an area of sites sacred to a number of Native communities will soon be made available to oil exploration.

Sites may also be destroyed in order to develop the region's tourism industry. Mount Shasta's expansion of skiing facilities destroyed religious areas used by various indigenous

communities in California. Anthropologists, Native religious leaders, and concerned citizens have fought the destruction of these sites on religious grounds.

According to the Supreme Court, however, the 1978 Religious Freedom Act does not cover geographical religious sites. As a result, sites that are located on public and private lands receive no special protection.

In some cases, however, public agencies are attempting to accommodate Native religious activities at sacred sites. One of the best-known examples is the effort of the National Park Service to accommodate the use of Devil's Tower by both tourists and Native peoples. This igneous outcrop located in Wyoming has religious significance for numerous Native tribes. It is also a popular place for climbing enthusiasts. Most of the religious ceremonies take place during the month of June, which was also the peak season for climbing the tower.

Two issues concerned religious leaders: that the distraction caused by the climbers weakened the connection between the prayers and the area's spiritual power, and that the pounding of pitons into the face of Devil's Tower disrespected the sacredness of the place. As a result, the National Park Service, which oversees Devil's Tower, requested that during the month of June, tourists forgo climbing the Tower. In addition, they strongly suggested that climbers reuse pitons already in place or obtain a permit to hammer more pitons into the rock's face. This strategy led to a significant drop in the number of climbers practicing their sport during the month

of June. Unfortunately, in 2004, the number of climbers rose.

Native American Religions

Native American religions have undergone numerous changes since contact. In the 1900s, as anthropologists tried to salvage information about the traditional religious life of Native peoples, the government was busy trying to eradicate “paganism.” Sun Dances, giveaways, potlatches, ceremonial clowns, and pilgrimages were being outlawed on all of the reservations. As these types of religious expression became seditious, many Native peoples converted to Christianity or joined newly emerged religious movements. One of the most contentious religions to gain popularity is the Native American Church. Using peyote, a type of cactus that grows in northern Mexico and southern Texas, as a sacrament, members of the Church participate in group prayers, songs, healing ceremonies, and Bible readings.

Because peyote has been classified periodically as an illegal drug by the federal government, and sometimes by state governments as well, the Native American Church has undergone periods of persecution. In 1918, Native peoples, anthropologists, and concerned citizens halted legislation to outlaw the use of peyote. With the help of James Mooney, an ethnologist with the Bureau of American Ethnology, practitioners of this religion incorporated the Native American Church. This strategy provided a modicum of protection against religious persecution.

A more complicated situation occurred when the Navajo Tribal Council outlawed the presence of the Native American Church on the reservation. Not until the 1960s did the Navajos’ tribal council adhere to the U.S. Bill of Rights guarantee of religious freedom. Finally, in the 1990s, President Clinton passed an executive order that protected members of the Native American Church from prosecution by the states for ingesting peyote.

Economic Development

Tribal economies have had a difficult time, particularly because they lost such a vast amount of land between allotment in 1887 and the Indian Reorganization Act in 1934. Obtaining capital for economic ventures is difficult for a number of reasons. One of

the most daunting relates to the fact that most tribal land is held in trust by the federal government. Other issues stem from the lack of infrastructure to get products to market, and conflicts with state governments.

Responding to these problems, President Nixon passed the Indian Self-Determination and Education Assistance Act in the 1970s. Basically, this Act transferred some power from the Bureau of Indian Affairs to the tribal governments. As a result, tribes can negotiate leases with external companies, contract their own educational services, and try to attract businesses onto the reservation.

Gambling, which has an illustrious history among many Native communities, has become an important area of revenue for many tribes. Since the 1980s, when the Indian Gaming Regulatory Act was passed, tribes have been permitted to operate one to three classes of gambling on reservation land. Class I gaming recognizes social gaming, often in connection with ceremonial activities that offer minimal monetary values. For example, in some communities, such as the Navajos and the Comanches, gambling has a spiritual dimension. Among other tribes, wagers are placed on hand games. Currently, tribes regulate this type of gambling.

Class II gaming, which includes bingo, pull-tabs, and lotto-style games, is under the jurisdiction of tribes and the National Indian Gaming Commission. Class III gaming, which involves casino-style games, requires approval by the tribe, the Indian Gaming Commission, and the state in which the activity will occur. Problems arise if the state does not allow Class III gaming. For example, in Nebraska, the Santee Sioux tribe has been running lottery-style gaming on its reservation. The state deemed the tribe’s actions illegal, and the Supreme Court ruled in favor of the state.

Another obstacle to establishing gaming operations is lack of funding. Loans may be obtained from the Bureau of Indian Affairs, or joint ventures between tribes or between a tribe and a state have been established in order to operate casinos.

For some tribes, casinos have been an economic boon. As competition increases, however, casino revenues have begun to decline. In some states, such as Minnesota and Wisconsin, numerous Native-owned casinos operate, and the market has become saturated. Many states wanting to share a larger portion of the gambling profits have constructed their own

casinos. When this occurs, the profit margin of Native American gaming diminishes further.

Native American Graves Protection and Repatriation Act

During the 1970s, Native peoples began to dispute anthropological perspectives of Native peoples and also to raise ethical concerns about research practices. Particularly contentious were the countless cultural objects with varying degrees of significance, skeletal remains, and photographic images of Native peoples that had been collected by researchers. Many Native peoples expressed anger that an estimated 600,000 of their ancestors' remains were being stored in universities, museums, and private collections in the United States.

Through the efforts of Native peoples, anthropologists, and concerned citizens, the Native American Graves Protection and Repatriation Act (NAGPRA) was passed in 1990. This federal legislation demanded the repatriation of skeletal materials and objects sacred to a community or an individual. Only federally recognized tribes are recognized as repositories for these returned items. In addition, these tribes must be able to prove a direct connection to the ancestral remains or culturally significant artifacts.

The controversy surrounding Kennewick Man, also known as the Ancient One, illustrates some of the problems with NAGPRA. Found in 1996, this skeleton of an adult male was dated to around 8,000 years ago. Using NAGPRA as their justification, members of the Confederated Tribes of the Umatilla, Wanapum Band, Yakama Confederated Tribes, the Nez Perce Tribe, and the Colville Confederated Tribes requested the reburial of this skeleton. Some members of the anthropological profession fought this request. According to their argument, no proven linkage could be documented between current Native populations and a skeleton dating 8,000 years ago, it could not be shown that these remains were Native American, and the remains could provide valuable information about the peopling of North America and the health of early communities.

At this point, the Native tribes have lost their bid to rebury Kennewick Man. It is unclear at this time what sort of effect this will have on future anthropological work with Native peoples in the United States.

NATIVE STUDIES

Native studies is a relatively new discipline. Although there is no common definition, it is generally distinguished as dialogue between Western and Aboriginal perspectives to a critique of Native-state relations. Many focus on the need for an Aboriginal perspective that encompasses Aboriginal history grounded in colonization, traditional knowledge and language, Aboriginal rights, and decolonization focusing on healing and wellness. Native studies contributes to an awareness of issues, priorities, and events as they relate to Native peoples. Others see Native American studies as a critique of dominant society, history, and relations. The term *Native studies* is used primarily in Canada to mean a study of Aboriginal peoples, defined in the 1982 Canadian Constitution as Indians, Métis, and Inuit. In the United States, frequently used terms are American Indian studies; Native American studies; or, alternatively, Indigenous studies, meaning a study of Native American peoples or Indigenous peoples internationally. Emerging from disciplines such as history, ethnohistory, and anthropology, it is touched upon by other fields, such as political science, law, art, community development, social science, and medicine. Native studies has become multidisciplinary and holistic in approach. Native academics are currently pushing the boundaries of Native studies to include academic inquiry written in the Native languages and informed by their traditional knowledge. There has been a movement

by Native peoples to establish their own institutions of higher learning.

Recognition for the Need for a Separate Discipline

Acknowledgment for Native studies separate from other disciplines was first shown in the late 1960s to early 1970s. Previously, Native issues had been discussed almost exclusively among anthropologists, ethnologists, and historians. According to Noel Dyck, these early interests included traditional ethnology, acculturation studies, and Native-state relations. Anthropologists and historians first attempted to reconstruct, analyze, and document the precontact life before extensive European incursion. Ethnology consists of the examination of acculturation among Native communities. Native peoples were forced to assimilate and integrate into Euro-Canadian and Euro-American culture, as well as having to abandon their own culture and languages in order to be a part of the national whole. Fieldwork was conducted concerning the changes that were taking place within the Aboriginal communities brought about by assimilation policies and practices. The third category is studies of Native-state relations, which focus on the characteristics of the relations between Native peoples and the government, institutions, or agencies. A large topic of interest is the difficult issues of land claims, Aboriginal rights, and federal Native policies.

During and after World War II, it became apparent that tensions between Native peoples and governments were problematic. Again, anthropologists began to investigate changes caused by these relationships and state agencies, the Department of Indian Affairs (Canada), and the Bureau of Indian Affairs (U.S.). There was recognition of changes taking place with Native peoples at the community and individual level. Scholars explored the activities, procedures, and administration of Native affairs at all levels of government. Most of the published material on Native peoples before the 1970s was written by anthropologists employed by museums, universities, and the government, and read mainly by these scholars.

Even though research was based on the lives of Native Americans, most results or analysis never reached the Aboriginal communities themselves. In the 1970s, Native leaders voiced their concern over the anthropologists working in their communities. They were tired of being studied to death by outside

experts, and they wanted to have ownership and control over, access to, and participation in the research in their communities. This became a new development in research—anthropologists' and other researchers' roles have shifted from power and decision-making roles to partnerships with Native communities. Today, Native communities are establishing protocols and bodies to manage research done in their communities. New bodies are formed, such as elders' committees to approve and oversee research to legislation to regulate research. Many communities are insisting on final joint approval of research results conducted in their territories. These measures are in place because of past abuses and misappropriation of culture and knowledge. Since the 1990s, there has been a growing concern from Native communities over protection of their traditional knowledge under intellectual property and cultural rights laws and declarations, particularly their medicinal knowledge. Internationally, there has been growing interest because of unauthorized reproduction of traditional designs, the publishing of secret knowledge, and issues around access and benefits. These and other issues are being discussed and negotiated at meetings of the World Intellectual Property Organization and other international venues.

In the past, states have sought to resolve the "Native problem" by eliminating Native rights, resulting in attention to the need for Native rights protection, legal decisions protecting those rights, and identification of the need for Native studies. The 1969 Canadian government White Paper, in fact, proposed to solve the "Native problem" by eliminating Indian rights granted under the Canadian Indian Act of 1876 and transferring administration to provinces and territories. The resulting public and Native outcry brought attention and extensive media coverage to Native issues across the country. The United States had implemented a similar termination policy prior to this, but eventually it was overturned. In the United States, Native Americans were granted citizenship in 1924; in Canada, citizenship was not granted until the 1960s.

Also, in 1969, Native American literature boomed with the publication of numerous protest books written by Native authors, many of which became bestsellers. During the same year, with the increase of interest in Native issues, three postsecondary institutions began to offer Native studies programs: the Navajo Community College and the University of

Minnesota in the United States, and Trent University in Canada. These schools would mark the beginning of a growing field within social sciences.

In the 1970s and 1980s, Native studies literature by anthropologists was predominantly ethnohistory, ethnology, community studies, and Native-state relations. There were literary and oral accounts of life histories, detailing the positive and negative impacts of the social, economic, and ecological consequences caused by colonization. Ethnological studies focused on Native cultural practices and beliefs. This expanded to studies of social organization, kinship, and domestic relations. There was some literature on traditional botanical knowledge, traditional medicine, and material culture. There was much interest in the significance of traditional economic activities such as hunting, fishing, and trapping. Anthropologists conducting research in communities considered themselves participants in these studies, which typically looked at change and adaptation within specific Native communities compared to other Native communities' experiences and identities.

Topics and Issues Discussed Within Native Studies Courses

The purpose of having Native studies as a separate field resulted from the hugeness of the task and the relevance to the national agenda. The Native and academic communities recognized that a large portion of North American history and experience was not being studied and told. Native studies was absent from school curricula and education, and what was being taught was biased and simply inaccurate. Native peoples also wanted their story and perspective to be taught as part of a national decolonization process. Native students and leaders demanded separate programs to teach their traditional lifestyles and perspectives in educational institutions. They wanted Native studies programs that taught their histories, philosophies, language, and traditions. These programs—situated in academia and accessible to the wider population—would allow for a greater understanding of Native peoples in a national context. The discipline would not only educate non-Natives by acknowledging misconceptions and stereotypes associated with Native Americans, but also serve as a means to acknowledge that Native peoples have a significant national heritage and played a central role in the founding and molding of the North American history

and culture. For Native students, their culture is celebrated, their history forms part of the national history, colonization is understood in the context of decolonization, and hope is restored for the healing and wellness of Native peoples.

Native studies has grown to include history, traditional and contemporary health and healing, art and literature, political science, business, law, linguistics, economics, and environmental science. There are now a number of Native Studies departments across North America, and in addition, many academic departments and disciplines now include Native studies scholars and courses. The result has been the indigenization of other fields and disciplines with both Native and non-Native scholars. This is indicative of the relevance of Native perspectives and knowledge on national issues and what traditional knowledge brings to ecology, science, law, development, and other fields.

The history of Native peoples is an integral part of Native studies. Understanding how Native peoples adapted and evolved from precontact to postcontact periods is critical to understanding the present. A thorough examination of Native peoples' history allows North Americans to become conscious of the magnitude of influence that Aboriginal peoples had on North American society. Native peoples have made contributions to the food we eat, our language, our institutions, our place names, and our view of the world. Native studies gives us another look at history with Native peoples as participants, recognizing their struggles, injustices, and inequalities exclusive of former biases and stereotypes.

The history of Native peoples' health is central to the history of the Americas. At contact, there was a huge decline in Native populations because they had no natural immunities to European diseases, such as smallpox and influenza. Historians have speculated that without great losses in Native populations, the history of the Americas would be more like China's, with Europeans making only minor incursions at the edges. Native peoples still have the poorest health compared to the rest of the population. The history of their health falls into two major periods: the reservation period, characterized by deaths from tuberculosis caused by poor nutrition and inadequate housing; and the past 50 years, characterized by heart and respiratory diseases and diabetes from a poor diet and inactive lifestyles. Poor health has contributed to colonization. Assimilation policies directed at Native

peoples, such as outlawing traditional culture and residential schools, have contributed to their high suicide rates and substance abuse. In response to ill health, Native peoples are revitalizing their language, culture, and healing ways. There have been some remarkable turnarounds in Native communities as a result of using traditional healing techniques such as healing circles and sweats and purification ceremonies.

Art and literature have created effective dialogue between Natives and non-Natives, contributing to growing awareness of Native issues, culture, and teachings. Art has always been a source of expression and communication, beginning with trade in Native products such as canoes, baskets, and so on to souvenirs such as beadwork and leather products. Contemporary Native art includes paintings, jewelry, and traditional arts, such as totem poles and masks. Today, Native arts participate in all areas of art, sculpture, music, dance, and literature.

Native peoples are said to be the first ecologists. Native concepts such as a living earth, making decisions for future generations, and living in harmony have made a significant impact on how the world sees the environment. Native peoples are making contributions to the environmental movement and environmental science. The Inuit in arctic Canada are noticing significant changes in the environment caused by global warming, such as shorter winters. The Inuit have expressed their concerns internationally about the changing environment and the danger of toxins in their food chain that affect their way of life.

Mi'kmaq scientists in Cape Briton Island have studied their environment and teamed up with local communities to reverse the adverse effect of polluted waters and a decline in shellfish. Scientists are working with traditional knowledge holders to improve the environment, knowing that these people have accumulated knowledge over hundreds of years.

Native studies now covers a wide range of disciplines and fields of study. There are Native studies academic journals, and it is clearly a growing field of scholarly study. Anthropologists and historians continue to work, but their methods have changed; methods such as participatory action research and research partnerships have replaced older methodologies. Native studies continues to be a catalyst in informing and educating the public and strengthening Aboriginal communities.

NATUFIAN CULTURE

Since Dorothy A. E. Garrod's 1928 excavations at a cave in Wadi en-Natuf (located about 10 miles northwest of Jerusalem), archaeologists have continued to define and explain the distinctive cultural phase that is called "Natufian." As the type-site for this cultural subdivision of the late Epipalaeolithic period, Shuqba Cave's Layer B yielded a configuration of material remains that has been discovered at a number of sites in the Levant. The behavior reflected in those remains represents a very significant step in human prehistory, because the Natufian people stood at the threshold of the "Neolithic Revolution," just before the Near Eastern economy shifted dramatically as a result of plant cultivation and animal domestication. The landscape surrounding these Natufian sites, located primarily in the region whose southern limit runs across northern Sinai into southern Jordan and then stretches to the Euphrates Valley in North Syria, provided the conditions for the relatively rapid transition to plant and animal domestication. Along with Shuqba Cave, in Wadi en-Natuf (which is still under investigation), important Natufian sites are Beidha, Hayonim Cave and Terrace, Ain Mallaha, Salibiya I, Nahal Oren, el-Wad and Kebara Caves (Mount Carmel), and Tell Abu Hureyra and Mureybit (in Syria).

Scholars have reached general agreement concerning the material components of a Natufian site. On the basis of the early excavations in the caves of Mount Carmel and in the Judaeen hill country, Garrod (and other pioneering researchers) identified this pivotal culture by means of a distinguishable inventory of stone and bone artifacts and mortuary practices. It is clear that the Natufian phase is transitional between the end of the Epipalaeolithic (the so-called Geometric Kebaran cultural complex) and the earliest stage of the Neolithic Period (defined as Pre-Pottery Neolithic A [PPNA] in Kathleen Kenyon's

work at Jericho/Tell es-sultan). By the nature of the case, there is some variation in the actual dates that are proposed to define this Natufian transition, although about 12,500–10,200 BP is a well-established range and a reasonable compromise.

There are further differences of opinion concerning the geographical range of a distinguishable Natufian artifactual and behavioral inventory; this has led to more chronological wrangling and the identification of Natufian and early Neolithic subdivisions, and distinctive but clearly related regional variations (for example, Harifian culture, in the Negev and Sinai). The most interesting debate regarding this Natufian phase concerns various factors that allowed/caused a segment of the Levantine population to give up its nomadic ways and adopt a sedentary lifestyle. In this important discussion, the most contentious question concerns the role of climate change (for example, the impact of the “Younger Dryas” on the Near Eastern environment as the determinative factor in demographic changes and the shift to cereal cultivation in the Natufian–PPNA transition).

Because of abundant food resources in the late Epipalaeolithic period, the Natufian population adopted a diversified subsistence economy that was based on hunting, fishing, and gathering. Their stone and bone tools enabled them to forage more intensively and settle down in permanent villages, although seasonal movement and the use of temporary camps probably continued in some areas. In this era, just before the Neolithic transformation took place, the diet of Natufian hunters and gatherers included meat from small game, gazelle, goats, birds, and (occasionally) large herbivores (among other animals). Such prey was often supplemented with fish and mollusks. Bones recovered from Natufian sites make this part of the picture clear, but seed remains are not as plentiful. Still, there is evidence for widespread consumption of nuts, legumes, and wild barley and wheat (among other plants). Because of this relative abundance of wild foods, the Natufian people could live in year-round villages before agriculture began.

As noted above, the distinguishable material components and behavioral patterns at sites associated with Natufian culture include a number of categories.

Small villages consisted of circular houses with stone foundations and organic superstructures. Some settlements include stone-lined or unlined pits, which have been interpreted as silos, although that was not necessarily their function in every case. Natufian

sites include heavy limestone or basalt grinding implements of various kinds, which were necessary for food processing. Since Garrod’s work in Wadi en-Natuf, a key feature of a Natufian settlement is the distinguishable lithic industry, in which microliths and geometrics (including Helwan lunates) are present in large numbers. Of course, this flint toolkit is not unique to the Natufian culture, but flint sickle blades made their appearance for the first time. These sickle blades, which were hafted into bone or wooden handles, were used in the intensive collection of wild grains and often include the telltale sickle gloss that results from usage. The Natufian bone industry was also well developed and consisted of fishing hooks, harpoons, awls, needles, and pendants.

Natufian villages are characterized by the accumulation of considerable debris and the skeletons of rodents (i.e., commensalism), and graves and cemeteries were also present in these settlements. Mortuary practices varied widely, in terms of grave location, composition, mode of inhumation, and burial position; variations in the ornamentation found on some skeletons (for example, shell and stone jewelry) point to some level of social or familial differentiation. Simple forms of art were part of the Natufian cultural complex and included carved stone and bone figurines. Although it was practiced on a limited scale, long-distance trade was involved in the exchange of obsidian, shells, and stone for certain beads.

Naturalism is the term that summarizes the coherent philosophical application and generalization of the

methods and conclusions of the sciences. Naturalism is a tendency among thinkers, one that spans most disciplines of thought. Naturalism is not a closely defined school of philosophy, as materialism and idealism have tended to be. Thinkers identified as naturalist often have little else in common.

The principal feature that naturalist thinkers share is an appreciation of the value of grounding their methods in the sciences, because of the heightened chances of securing reliable information, which in turn yields reliable knowledge. Following the thoughts of Dale Riepe, we can make some more specific points: The naturalist places a high value on reason and sense experience as the most reliable avenues of knowledge; the naturalist believes that knowledge is not mystical, innate, or intuitive; the naturalist believes that the external world, of which humans are an integral part, is objective and therefore has existence apart from anyone's consciousness; and the naturalist believes that the world manifests order and regularity, and that, contrary to some opinions, this does not exclude human responsibility. This order cannot be changed merely by thought, magic, sacrifice, or prayer but requires the actual manipulation of the external world in some physical way. The naturalist also rejects supernatural teleology. The direction of the world is caused by the world itself. And finally, the naturalist is humanistic. Humans are not a mirror of some supernatural deity or absolute principle but a biological existent whose goal it is to do what is proper for humans' continued existence and fulfillment. These goals can be determined in a naturalistic context by the moral philosopher.

Dale Riepe's observations were made before embarking on a study of naturalism in Indian philosophy, which illustrates the cross-cultural and transnational nature of naturalism.

This understanding of naturalism involves the rejection of all manifestations of supernaturalism *in their capacity as truth-claims* on the grounds that they are often culturally specific, whereas naturalist claims are applicable to all nature. Furthermore, supernaturalist claims cannot be repeated, tested, or verified, and in the end, they rely upon mere assertion. However, this does not involve a complete rejection of supernaturalism as a factor worthy of consideration. Supernaturalism is a valid subject of study as a cultural phenomenon within naturalism—a way some people choose to interpret the universe. But it is not an alternative to naturalism.

Historical Overview

The most notable feature of naturalism is its transcontinental origins. Where most philosophical systems have their roots in one culture and bear the marks of that culture's emphases, naturalism can trace its origins back to ancient India, China, and Greece.

A credible case can be made for Uddalaka as the first recorded naturalist. His dates are far from certain, and doubts even about his historicity have been raised. The least unlikely dates for Uddalaka are about 640–610 BCE, which means that he predates the better known Carvakas of India and pre-Socratic Greek philosophers. Uddalaka was a teacher-philosopher who enjoyed disputation and developed a sizable following. He taught that breath was the essential element in a human being. Many idealist thinkers of the time held that thought is the essential element, but Uddalaka argued that thought is itself made up of matter in the same way that breath is. He was also skeptical about reincarnation. Uddalaka provided the first versions of a monistic universe, atomistic physics, and deliberation based on appeal to what is physically observable rather than to mystical slogans.

Shortly after Uddalaka came the Carvakas, the materialist school of thought (*darshana*) in India and one of the oldest materialist traditions in the world. Carvaka is thought to be the name of the founder of the school, but nothing is known of him beyond his name, and even his historicity is uncertain. Tradition has Carvaka as the moral accuser of Yudisthira, a leading figure in the Hindu epic, the *Mahabharata*. Alternatively, Carvaka also means “sweet-tongued,” or “pleasant words,” which may refer to the general perception of Carvaka philosophy as hedonistic.

Carvaka philosophy regards the universe as interdependent and subject to perpetual evolution. Central tenets of the Carvaka school are the following: Sacred literature should be regarded as false; there is no deity or supernatural; there is no immortal soul or afterlife; karma is inoperative and illusory; matter is the fundamental element; and only direct perception, and not religious injunctions or sacerdotal classes, can give us true knowledge. The aim in life is to get the maximum amount of pleasure from it. This had various interpretations, from unalloyed hedonism, on one hand, to an altruistic service of others as a means of maximizing one's own happiness on the other.

Most authorities acknowledge that the Carvaka tradition has saved Hinduism from lapsing into dogmatism or ritualism and has operated as an important irritant to majority patterns of thought. Although overtly expressed naturalistic thinking in India died out, a naturalistic strand of Indian thought persists to the present day, to the extent that India has no strong moral prohibition against naturalist thinking, which is often a feature of Western thinking.

Chinese thought to this day reflects a naturalistic bent. Chinese thought sees laws in physical nature and in human nature, but has no sense of a supernatural lawgiver. The logician Hui Tzu (380–300 BCE approx., Hui Shih in old spelling) spoke of the universe as “that which has nothing beyond.” This means that all things are part of the universe, the central precept of naturalism. More striking even than this, however, are the concerns of Chinese thinking. Whereas Indian thought is always tempted toward metaphysics, Chinese thought is more about human nature and the ethical imperatives for a sound state, family, and individual. Kongfuzi (551–479 BCE, Confucius in Latinized spelling) urged his readers not to worry about the gods unduly, but to get on with life. Kongfuzi, long recognized as China’s most influential thinker, was concerned with establishing a good society. Such a society can be based only on good government, which in the end relies on harmonious human relations.

In Greece, the earliest naturalist thinker was Thales (approximately 625–545 BCE), who is also credited (not entirely accurately, as we have seen) as the first philosopher. Thales was unprepared to accept the received wisdom about how the universe works. The historian Herodotus tells of a battle that came to an abrupt halt because of an eclipse that took place according to a prediction made by Thales. This established his reputation and, more importantly, the reputation of naturalism as a successful way of understanding the world. The eclipse took place on May 28, 585 BCE, and this date has been given as the day science was born.

Thales was followed by a succession of thinkers that developed different theories of how the universe works. Their theories differed but the thinkers’ desire to understand the world in naturalistic terms brought them together.

For reasons beyond the scope of this topic, the naturalists of India, China, and Greece were overwhelmed by a reaction from idealist philosophers and

religious apologists. For almost 2,000 years, the naturalist understanding of the world was dormant. The works of its leading thinkers were destroyed and forgotten, and a dark age of superstition and religious dogmatism spelled an end to the intellectual developments of the ancient world. But although the naturalist world was dormant, it did not die altogether. Some of its works survived and were rediscovered between the 12th and 15th centuries. The rediscovery of the works of the ancients stimulated a renewal of interest in the world and in humanity. The most notable of these flowerings is known as the Renaissance, which took place roughly between the 1370s and 1600, and especially between about 1400 and the 1520s.

Since the Renaissance, naturalism has returned to the center stage of all intellectual and scientific life. Three great revolutions in naturalism have been instrumental in achieving this. The first of these great realignments of thought was what is now called the Copernican revolution. Following discoveries by Copernicus, Kepler, Galileo, and others, no longer was it credible to see Jerusalem, or even the entire planet Earth, as the center of the universe. Instead, it has become apparent that our planet is one among many billions in a universe that is many billions of years old.

The Copernican revolution was followed in the 19th and 20th centuries by the Darwinian revolution, which continued the trend toward the naturalistic outlook becoming the normative way of understanding the universe. If the Copernican revolution meant that humans were no longer the center of the universe, then the Darwinian revolution meant that humans could no longer see themselves as sitting at the peak of the hierarchy of living creatures. The ancient world subscribed to a hierarchy later known as the Great Chain of Being, which went in a line from God or gods, downward through men, then women, higher animals, lower animals, plants, and rocks. But like the earlier habit of seeing the earth as the center of the universe, the Great Chain of Being hierarchy was supported by a supernaturalist outlook that new facts no longer supported. It was now apparent that humans were more like the other animals and shared a planetary ecosystem with them.

The third great naturalist revolution is still unfolding today. It is the revolution in genetics and neurophilosophy, which is rendering obsolete the last major prescientific conceit of our having incorporeal souls and a mind, which is not the same thing as our brain. These three great revolutions in our understanding

have elevated naturalism to its current position as the normative outlook for all serious thought.

Cosmological and Methodological Naturalism

But if naturalism has won the day over its pre-scientific predecessors, this does not mean that the intellectual challenges are over. The debate now is centered on the features and priorities of naturalism. Contemporary naturalism is seen as consisting of two aspects, the relations between which are close or not, depending on one's philosophical outlook. There is, on one hand, *cosmological naturalism*, which is dedicated to providing a coherent cosmological picture, a worldview that is based on reliable knowledge and without recourse to metaphysics or supernaturalism.

Cosmological naturalism is an outlook on the world that is informed by, although not exclusively composed of, the sciences. John Passmore, one of the 20th century's greatest historians of philosophy, said that naturalism emphasizes the interconnectedness of things. Cosmological naturalists seek to understand the interconnectedness of things without recourse to supernaturalism or subjectivism. As Richard Dawkins has devoted his career to showing, our orderly universe, a universe indifferent to us as a species "is a more beautiful, more wonderful place than a universe tricked out with capricious *ad hoc* magic."

Cosmological naturalism tends to be atheistic or agnostic on matters of the existence of God or gods, and indeed of all other supernatural phenomena. A prime example of cosmological naturalism from the ancient world is *De rerum natura* (*On the Nature of Things*), a poem by Lucretius (100–55 BCE) that was completed in 60 BCE. *De rerum natura* gives expression to the atomist view of the universe as originally expounded by Democritus and adapted by Epicurus. In China, cosmological naturalism has its finest expression in the works of Wang Chong (27–97 CE), whose work *Lunheng* (*Discursive Equilibrium*) was written over 82 and 83 CE. Wang Chong argued that natural events are simply that—natural events without any supernatural implications. He opposed the widespread superstitions about attracting fortune to oneself and preventing misfortune. Moral virtue has no essential connection with personal destiny. Wang Chong insisted that any theory must be tested by concrete evidence and tried at all times to argue in a rational manner, supporting his claims with appropriate levels of evidence.

The ideas of Lucretius and Wang Chong have been built on through to the present day and are best represented by philosophers such as Daniel C. Dennett, mathematicians such as Norman Levitt, psychologists such as Steven Pinker, scientists such as E. O. Wilson and Richard Dawkins, and novelists such as Margaret Atwood.

But there is also *methodological naturalism*, which is not concerned so much with constructing worldviews as it is in determining a valid method of acquiring reliable knowledge. This used to be called the "scientific method." In general terms, we see that the ancient naturalists were more overwhelmingly methodological naturalists than they were cosmological naturalists.

Among contemporary philosophers, Richard Rorty, Hilary Putnam, and Kai Nielsen have been cosmological naturalists without being methodological naturalists. This is usually because of an unwillingness to accord science a privileged position as an arbiter of reliable knowledge. They have sought, in Nielsen's words, a naturalism without foundations. It is rarer, but not impossible, for people to be methodological naturalists, that is, to accept the use of empirical methods to ascertain reliable knowledge, while not employing that methodology to then build a worldview from it.

One of the main reasons some philosophers wish to distance cosmological from methodological naturalism is that they fear an unwarranted scientism in the methodological program. Kai Nielsen is one of the most recent and lucid articulators of this view. Following Putnam and Rorty, Nielsen questions what is meant by "scientific method," and he is suspicious about what he sees as a tendency to freeze out art, morality, and religion "while naturalizing them in the spirit of an uncompromising atheism." However, the writings of those who embrace metaphysical naturalism and methodological naturalism show no sign of this fear having any grounding in fact.

What actually is methodological naturalism? Tad Clements has ascribed the following characteristics: intellectual curiosity; the desire for defensible, reliable knowledge; the tendency to think of the subject of the study as related to other elements of nature in lawful ways, that is, thinking naturalistically; the recognition that anyone may be mistaken; a tendency to skepticism; a predilection toward manipulating conditions so as to be open to experiment; a preference for logical simplicity; an aversion for vague or confused

concepts; a preference for the ideal of moral neutrality when seeking knowledge; the tendency to avoid anthropomorphism.

Ironically, these points we have used to itemize methodological naturalism were employed by Clements to illustrate what he called scientific method, so we need not take too seriously differences between the two. And Clements's account of methodological naturalism carries enough caveats about the uncertainty of our knowledge and the avoidance of unwarranted dogmatism to reassure those worried about the dangers of scientism.

Methodological naturalism needs to overcome two main problems in order to establish its value. First, it needs to demonstrate that the mechanics of methodological naturalism—mathematics and logic—are empirical. And second, it needs to show that nonempirical methodological principles used outside the sciences are unnecessary. The standing of naturalism suffered somewhat during the 1960s and 1970s, when the first of these conditions went through a period of difficulty.

These objections have largely been resolved, and there are now few outside the more radical exponents of science studies or variations of postmodernism who would question the notion that science does involve a gradual accumulation of knowledge, and that we can say we know more now than was known at some point in the past. From this, it follows that we have had more opportunities to weed out error from our account of the universe. That is not to say that our current knowledge is all true, let alone perfect, simply that more is known than was once the case. And to the degree that this is correct, one can speak meaningfully of progress.

The other important point is that science has shown its validity by being the instrument by which so much of this reliable knowledge has come to us. Under the influence of the American philosopher of science Thomas Kuhn, claims like this were problematic for a while in the 1960s and 1970s, but Kuhn's account was unable to provide an explanation of how scientific knowledge *does* increase if not by the steady accumulation of knowledge by people working toward a goal of attaining the truth. It ends up that the traditional explanation was right after all: There is an objective reality out there, and, through science, we are slowly getting a better idea of how that reality operates.

Then there is the argument that says that any explanation that goes over and beyond a naturalist

explanation violates Occam's Razor, which requires that we do not unnecessarily multiply entities in explanation. Centuries earlier than William of Occam, the Greek atomists, followed by Strato of Lampsacus, employed Occam's Razor when they denied that the phenomena of the universe can be explained by appealing to some entity said to be beyond the universe. Antony Flew, following David Hume, has called this the Stratonician Presumption. Flew used this argument in the context of debating the existence of God, but it is clear it has a wider application. Atheistic naturalism, Flew argued, "must have at least this initial priority over theism [because] it is the more economical view. The theist as such postulates more than the atheist; and, in consequence, the onus of proof must rest on him."

This approach has also been taken up by some prominent scientists and mathematicians. Norman Levitt has argued for what may be called a presumption of science. If the conclusions of science contradict with those of another belief system, then the benefit of doubt goes to the scientific explanation and the burden of proof falls on the supernaturalist explanation. On the face of it, this seems unacceptably arrogant. Why should science be accorded this sort of priority? Levitt's answer is simple. Because science works and has got an incomparably more reliable track record of providing accurate answers than any other system. Levitt's claim also becomes more understandable when we recognize that he is not making a distinction between naturalism and supernaturalism as two equally situated systems of thought. He insists that there is no "natural" way to distinguish the natural from the unnatural. In other words, the distinction between nature and culture is itself a cultural construct.

Quentin Smith has advanced a similar argument, but in the interests of the broader concept of naturalism. Smith maintains that naturalists have allowed opponents of naturalism—in his case, theistic apologists—to swing the argument so that theism becomes normative and naturalism becomes marginalized as skepticism about religion. In fact, Smith writes, it is naturalism that is normative, and the various theisms should be seen as skepticisms about naturalism.

As we have seen, Smith's argument on the normativity of naturalism goes back a long way. Bertrand Russell perhaps understood the problem most clearly when he noted that knowledge is an unimportant feature of the universe, and that a science that omitted to

mention knowledge is not going to suffer from any significant imperfection.

What Russell is reminding us is that the universe is a lot larger than is our knowledge of it. Or, to put it more bluntly, anthropocentrism is a serious flaw. It follows, then, that when laying out our intellectual foundations, we must begin with the method of knowledge that is the least inadequate in yielding good quality information about the universe. That has proved to be science. Naturalism is the study of nature in a way that is repeatable and that yields reliable knowledge. Naturalism is, as Paul Kurtz puts it, the philosophical generalization of the methods and conclusions of the sciences. And by virtue of studying nature on its own terms, naturalism avoids, for the most part, the faults that anthropocentrism inevitably brings with it.

This understanding of naturalism does not necessarily equate it with physicalism, which is the claim that only physical entities exist. The claim made by those who are both cosmological and methodological naturalists is not that there are only physical things, but that the methods of study of physical things have yielded the least inadequate information by which we may understand the world. This caveat also has important implications for the alleged conflict between a naturalist and nonnaturalist view of the world, whether it be supernaturalist, idealist, or subjectivist. The emerging discipline of evolutionary psychology is making exciting progress on this question. One of evolutionary psychology's principal findings is that religions are phenomena of nature, just as gravity, giraffes, and governments are. And like the last of those three examples, religion is also a human creation.

Naturalist Ethics

It is rapidly becoming clear that one of the most interesting areas of research and debate in the first half of the 21st century will be the field of naturalistic ethics. As noted earlier, the third great naturalistic revolution involves genetics, the brain, and what being human actually means. The ethical consequences of these fields of study are enormous.

But before beginning any discussion of naturalistic ethics, we need to ask, can we even speak of ethics derived from naturalism at all? Would this not run into the problem of the so-called naturalistic fallacy? This is an important and highly controversial idea,

first developed by David Hume, but made known by G. E. Moore (1873–1958) in his 1903 book *Principia Ethica*. Moore believed that any attempt to define “good” was bound to fail, because “good” is a simple, nonnatural (although not supernatural) quality that could not be analyzed. With this in mind, Moore was critical of some of the social Darwinist theories fashionable at the time that claimed to be able to derive notions of good from their readings of science. Moore drew on the insight of David Hume, who criticized the tendency to draw conclusions about what *ought* to be the case from information that speaks only about what the case actually *is*. A graphic example is the tendency of deformed animals to die or be killed by the mother (the “is” in the equation) as evidence that humans suffering from some disability *ought* to be similarly dealt with.

An important, though neglected, point about the naturalistic fallacy is that it applies not only to naturalistic theories but to *all* ethical theories. For instance, the claim made by many evangelical Christians that the Bible says X, therefore we ought to X, is an example. So, although the naturalistic fallacy has some worthwhile things to say about the more simple forms of inappropriate is-to-ought rationalizing, it is far from established that any attempt to treat the concept of “good” as something open to analysis is, by definition, mistaken. To take a simple example, polluted water causes illness in people, therefore we ought not to pollute water. Is this really such a bad argument?

We can, therefore, conclude that the naturalistic fallacy serves as a useful corrective to making unduly confident is-to-ought conclusions. But we should not shy away from using science as a tool to help us improve life and happiness on the grounds of a supposed fallacy in philosophy from a century ago.

Having decided that the topic of ethics derived from naturalism is valid, we then need to appreciate fully what is being excluded. All of the conventional items of supernaturalism are abandoned—an incorporeal soul, immortality, resurrection, reincarnation, karma. All of them are removed from consideration because they cannot be validated by any method recognized by methodological naturalism. These precepts are religious ones and are believed as an article of faith and/or cultural practice. This is an important first step, because only now can we see how naturalist ethics works. It also pushes into first place the value of humility, a cosmic humility when one takes on board

the implications of being thoroughly unimportant to the cosmos as a whole.

It was Bertrand Russell who articulated this understanding most effectively in some of his ethical writings. Russell urged us to take the longer view. Given that we can't presume any cosmic reward for ourselves, we must take the longer view and look at what is best for the universe as a whole.

Opponents have frequently criticized this view as "arid," "bleak," and lacking in consolation. The last criticism is valid, but the first criticism depends on one's point of view, and there is no necessary link between the two. What may seem arid to the religious believer is seen as realistic by the naturalist. It is a basic premise of naturalistic ethics that one should not believe *in* unless one can believe *that*. In other words, believing something that is untrue but consoling is a fatal subversion of any well-grounded ethics. But this understanding of the cosmos also provides something else with which naturalists are not often credited—an understanding of the tragic sense of life. Miguel de Unamuno (1864–1936) wrote a book by this title that was published just before World War I. However, Unamuno's understanding of the tragic sense of life was undermined when he then offered the full range of traditional Roman Catholic consolations.

In contrast, the naturalist cannot offer a range of supernaturalist consolations. This understanding has motivated some of the most moving and poignant writing. From Bertrand Russell's *A Free Man's Worship* to Rohinton Mistry's novel *A Fine Balance*, some of the more sensitive observers of the human condition have spoken of this fine balance between hope and despair that is the stuff of life. It has been this understanding that has motivated so many of the finest novelists and artists, such as Emile Zola, George Eliot, Arnold Bennett, Maurice Gee, and Iris Murdoch.

Existentialists also understood the central significance of the lack of sustaining consolations, but then could do nothing but counsel despair. Man is condemned to be free, Jean-Paul Sartre wrote, and he himself then spent his life working for political change and helping causes he thought worthwhile. But for so many existentialists, the slogan "existence precedes essence" was taken as an invitation to narcissism. Nothing mattered except creating one's essence; nothing mattered except oneself. This trend toward narcissism became even more pronounced with the advent of postmodernism, which allowed the next

step—nihilism—to present itself. Now, any sort of commitment to a cause or belief larger than oneself was dismissed as little more than an arbitrary snatch at one unwarranted metanarrative rather than another. The only alternatives offered were irony and wallowing in the detritus of a civilization declared by them to be tawdry.

We can now suggest some preliminary conclusions that can be drawn from this survey of naturalist ethics. Of the many articulations of naturalistic ethics, among the clearest was presented in 2003 by Gerald Larue, who also stressed the interconnectedness to which other naturalistic scholars have referred. Larue listed the main conclusions of naturalistic ethics as the following: We are one family, all life forms have had to learn to adapt, and we have a common world ecology.

Larue also concluded that our species has not yet learned to replace our native aggressiveness with aggressiveness for learning about and coming to terms with the limitations of our world ecology.

Naturalism in Art

Before concluding, it is worth returning to the observation made above that naturalism is understood in different ways in different disciplines. We can illustrate this by giving a brief outline of the way naturalism is understood in the visual arts. In the visual arts, naturalism is a term used to refer to the growing interest in portraying objects in nature, particularly the human figure, as the artist actually sees them rather than as exemplars of some ideal.

However, naturalism in art is not to be confused with realism, the accurate representation of nature. Naturalism as a complete and specific style in art reached its apogee in the second half of the 19th century, but naturalistic tendencies or emphases can be seen throughout the history of art. In this way, Egyptian or Assyrian reliefs can be naturalistic in the way human figures are represented, even though the reliefs are by no means realistic accounts of nature. And the romantic paintings of Caspar David Friedrich are naturalistic in their portrayal of nature, even though the inspiration for the paintings owes more to the Romantics.

The specific desire to portray humans naturalistically first found expression during the Renaissance when the idealized figures of Christ or the Virgin Mary

were replaced by figures with more human proportions. The work of Leonardo da Vinci (1452–1519) provides the finest illustration of this. It is not that naturalistically rendered works are free from idealization. It is more that whatever ideal values are being presented in the work are transmitted through the representation of people and objects as the artist experiences them.

In conclusion, we can restate the central points that constitute the naturalist worldview. Human knowledge is a fragile flower and forms a less-than-minimal part of the cosmos. From that core assumption, it follows that it is desirable that we adopt a form of knowledge that recognizes its fallibility and resists the temptation to disguise our ignorance by making unverifiable leaps in the dark. The default position goes to the naturalist option for a number of reasons. First, it is most in accord with Occam's Razor, which leaves supernaturalist systems with the burden of proof. Second, the methods of scientific inquiry are repeatable and testable with regard to circumstances of creed or belief, unlike supernaturalist systems, which are largely dependent on place, time, and station. And third, the record of science in providing reliable knowledge is superior to that of nonnaturalist systems. As such, science contributes most effectively to providing us with some reliable knowledge of the universe, without falling into the temptations of anthropocentrism and anthropomorphism. The worldview that emerges from this process is called naturalism.

The universe, including the planet Earth, was established by means of natural evolution; the process and the result of the Big Bang activity. Usually, nature is understood as something that originated naturally, that is, the opposite to culture or just the opposite to spiritual culture (human mind, activities). The term *nature* sometimes comprises the whole objective reality, including human society (i.e., even the so-called second nature). As it is used today, the word *nature* is not only rather inexplicit but also rather inaccurate. Its content doesn't imply that the Earth is connected with the universe; that humans, as a biologic species, are a part of the Earth environment; or that humans are organisms closely connected with the other live systems of the biosphere. It doesn't also reflect the scientific knowledge that only biosphere, as a whole, is the smallest, comparatively autonomous system capable of a long-term progressive development in time. Humans and other organisms living in the biosphere, individuals, populations, and species are temporary and nonindependent, dependent on the structure, integrity, and prosperity of the planetary biotic whole. Therefore, integrity and prosperity of the biotic whole are also critical for the human culture.

Nature is one of the oldest philosophic terms. The Greek word *physis* was an everyday term designating those things that originated naturally, without the influence of human activity. The Latin word *natura* was understood similarly. The Middle Ages interpreted both humans and nature as created by God. The theoretical interest in humans and nature was revived in Renaissance thinking, but the term didn't acquire any specific theoretical contents. Indeed, it has been disappearing from theoretical thinking since the end of the 17th century because of the high prestige of Newtonian physics. It seemed that it was finished as a term whose etymological root referred to birth and origination. It was also the influence of Descartes's nature-human dualism that forced the idea that humans, who learn about nature and transform it, don't belong in nature, that they are superior to it. Nature was understood as an expanse, as an indestructible substance and energy, as a substance where nothing new comes into existence ontically. The term *nature* was diluted in the ontologically more important term *substance*.

Development of the mechanical technology after the Industrial Revolution supported the idea that the character of natural events is best described by physics cooperating with mathematics. Yet even those categories of physics, such as body, force, distance, movement, acceleration, and so on, that were understandable to general thinking, reduced nature into bodies moving in space, into a mechanism without its own history, ontical creativity, and value. The emphasis upon the energy and mass conservation law, expressed by the well-known Einstein equation $E = mc^2$, concealed the fact of the natural evolution of the universe, that is, the irreversibility of time and the temporary character of structures.

The needs of establishing an adequate anthropology and of dealing with the conflict between culture and nature make us define nature in an evolutionally ontological way, not only as an objectiveness independent from humans but also as a human-including procedure, as a natural evolution embodying the irreversible constitutive time. If there is any deep sense in natural evolution, it is the construction of the grand structure of the universe, the creation of its large-scale physical order, including also the complete terrestrial abiotic and biotic orders.

For the purpose of the theoretical and value rehabilitation of the currently ill-defined term *nature*, we will have to make a difference between its two content layers: nature in the general sense—the universe—and nature in the specific sense—the Earth. This differentiation then offers a new reply to the old antique and medieval question: What is the position

of the Earth within the universe? It is possible to reply either from the traditional physical-mechanical viewpoint or from the new evolutionary-ontological viewpoint.

The first reply, which surpasses the antique and medieval geocentric viewpoints and is still considered to be the top performance of scientific knowledge, can be summarized in the following way: The Earth is a planet of the sun, that is, of a second-generation star; it is not a fixed center of the solar system or the galaxy or the universe. In fact, it is not a spatially significant body within the universe at all. Even our sun

is just a tiny and insignificant part of the universe, which, as a whole, in the large scale, is homogeneous and isotropic. It is the same in all directions, and it consists not only of hydrogen and helium, but also of a tiny amount of other elements that can be found even on the Earth. The surrounding universe is not animated; as far as we know, it lacks any signs of life.

The other, evolutionary-ontological answer to the same question seemingly contradicts the above-mentioned physical-mechanical characteristics of the Earth. It seemingly brings to life the old geocentrism because it returns those characteristics to Earth nature that it was wrongly deprived of by Newtonian physics: exceptionality, creativeness, and solemnity. It characterizes the Earth as a highly organized system of animate and inanimate features and subsystems, as a structure compatible with humans and as the only possible home to humans and human culture. The spatially insignificant position of the Earth within the universe has been connected with the narrow range of conditions that permitted the origination of life and its long, never completely interrupted evolution. This evolution also depends on the reliable functioning of the not-so-distant thermonuclear reactor—the sun. Biosphere is an open, nonlinear system powered with the energy of the sun, a continuation of the development of the natural abiotic evolution of the universe. The organizational complexity of the biosphere has grown gradually, in steps that couldn't possibly have been larger because they have been connected with both the more or less constant input of solar energy and the high degree of reliability of the genetic information transfer. Evolution also makes use of the nonreliability of the natural information transfer.

Current organisms are therefore the live historical memory of the long development of the biosphere. They seem to be concurrent bearers of its “spiritual and material cultures.” Evolutional conditions are not only encoded in their genomes, but also embodied in their body parts, tissues, and structures. This explains why there are serious informational reasons for the awakening of human responsibility for all culturally eradicated or endangered species, for a respectful approach of humans toward the Earth.

Life on Earth is the only large organism of which we are a part and whose health condition is rather critical because of our activities. Because we have destroyed most of the original ecosystems, we have seriously damaged not only the physical structure of life on Earth but also its memory, its informational

structure. We have destroyed a part of the genetic information of the current biosphere, which is the only bearer of its inner constitutive information. We have damaged the precious memory of live nature, which had appeared and integrated life a long time before the origination of our biologic species. The genetic information of planetary life serves as a barrier against its disintegration, and therefore, we are currently facing the gravest danger in all of human history.

Natural information is absolutely superior both to human life and to human social-cultural information. In the world where an ontically creative evolution operates at the background of a generally destructive process, the biospheric memory (the natural information) is an indicator of the development of life: It automatically expands and contracts, a part of its structure can be destroyed by a natural disaster or culture, but as a whole, it is as immortal as life itself. Contrary to that, humans—items of life—are mortal not only as individuals but also as a species. Without humans, even human works are mortal. Life on Earth cannot use and develop any human artistic or technical works without humans. The disappearance of humans will cause entropy of the human culture, its natural destruction.

NATURE, ROLE OF HUMAN MIND IN

Nature, at its microphysical level, constitutes the subject matter of quantum theory, also known as quantum mechanics. Never in the history of physics has there been a theory that has changed so drastically the shape of science as quantum mechanics; nor has there been a scientific theory that has had such a profound impact on human thinking. Since its inception in the early part of the 20th century, quantum mechanics has played, and still does play, a significant

role in philosophical thought both as a source of metaphysical ideas and as an important example of a scientific revolution. Thus, the advent of the quantum paradigm has gradually challenged the traditional philosophical substratum of science, the representational-visualizable description of microphysical entities and phenomena, the commonly perceived part-whole relationship that is built into classical physics, the relationship of cause and effect, the unrestricted validity of deterministic laws, and even the nature of physical reality and its independence from the process of knowledge.

Quantum mechanics is a statistical theory of the microscopic structure of matter. Within the standard framework, the codification “statistical theory” should not be understood as referring to our incomplete knowledge of the real physical state of a system, or to our computational insufficiency arising because of the complexities of the microphysical situation. On the contrary, it should be considered as an aspect of the *irreducibly probabilistic* behavior of matter at the microscopic level of description, as a genuine feature of reality that breaks with the apparent determinism of the classical Newtonian world. Quantum features such as noncommutativity, nonlocality, nonseparability, and the generalized phenomenon of quantum entanglement have been forcing us to revise radically the intuitive classical ideas about physical reality. According to our current understanding, for a consistent realist interpretation of quantum theory, the concept of realism must not be associated with ideas taken over from classical physics, such as atomism; localizability; separability; or similar philosophical presuppositions such as strict subject-object partition, mechanistic determinism, and ontological reductionism.

The Classical Conception of Nature

Classical physics is essentially *atomistic* in character. It portrays a view of the world in terms of analyzable, separately existing, but interacting self-contained parts. Classical physics is also *reductionistic*. It aims to explain the whole of forms of physical existence, of structures and relations of the natural world in terms of a salient set of elementary material objects linked by forces. Classical physics (and practically any experimental science) is further based on the *Cartesian dualism* of *res cogitans* (“thinking substance”) and *res extensa* (“extended substance”), proclaiming a radical

separation of an objective, external world from the knowing subject that allows no possible intermediary.

In fact, the whole edifice of classical physics—be it point-like analytic, statistical, or field theoretic—is compatible with the following *separability principle*, which can be expressed schematically as follows:

Separability Principle: The states of any spatio-temporally separated subsystems $S_1, S_2, \dots, S_N$ of a compound system S are individually well-defined, and the states of the compound system are wholly and completely determined by them and their physical interactions, including their spatio-temporal relations.

The aforementioned separability principle delimits the fact, upon which the whole classical physics is implicitly founded, that any compound physical system of a classical universe can be conceived of as consisting of *separable, individual* parts interacting by means of forces that are encoded in the Hamiltonian function of the overall system (determining the total energy of the system), and that, if the full Hamiltonian is known, maximal knowledge of the values of the physical quantities pertaining to each one of these parts yields an exhaustive knowledge of the whole compound system.

The notion of separability has been viewed within the framework of classical physics as a principal condition of our conception of the world, a condition that characterizes all our thinking in acknowledging the physical identity of distant things, the independent self-autonomous existence of spatio-temporally separated systems. The primary implicit assumption pertaining to this view is a presumed *absolute kinematic independence* between the knowing subject and the object of knowledge, or equivalently, between the measuring system (as an extension of the knowing subject) and the system under measurement. The idealization of the kinematically independent behavior of a physical system is possible in classical physics because of both the Cartesian-product structure of phase space, namely, the state space of classical theories, and the absence of genuine indeterminism in the course of events or of an element of chance in the measurement process. During the act of measurement, a classical system conserves its identity. Successive measurements of physical quantities, such as position and momentum, which define the state of a classical system, can be performed to any degree

of accuracy. The results combined can completely determine the state of the system before and after the measurement interaction, because its effect, if not eliminable, takes place continuously in the system's state space and is therefore predictable in principle.

Consequently, classical physical quantities or properties are taken to obey a so-called possessed values principle, in the sense that the values of classical properties are considered as being possessed by the object itself independently of any measurement act. That is, the properties possessed by an object depend in no way on the relations obtaining between it and a possible experimental context used to bring about these properties. No qualitatively new elements of reality are produced by the interaction of a classical system with the measuring apparatus. The act of measurement in classical physics is passive; it simply reveals a fact that has already occurred. In other words, a substantial distinction between potential and actual existence is rendered obsolete in classical mechanics. Within the domain of the latter, all that is potentially possible is also actually realized in the course of time, independently of any measuring interventions. It should be noted, in this respect, that this is hardly the case in the quantum theory of the measurement process.

The Quantum Conception of Nature

The Generalized Phenomenon of Nonseparability

In contrast to classical physics, standard quantum mechanics systematically violates the conception of separability. From a formal point of view, the source of its defiance is due to the tensor-product structure of Hilbert-space quantum mechanics and the superposition principle of states, which incorporates a kind of objective indefiniteness for the numerical values of *any* physical quantity belonging to a superposed state. The generic phenomenon of quantum nonseparability, experimentally confirmed for the first time in the early 1980s, precludes in a novel way the possibility of defining individual micro-objects independently of the conditions under which their behavior is manifested. Even in the simplest possible case of a compound system S consisting of just two subsystems, S_1 and S_2 , that have interacted at some time in the past, the compound system should be treated as a nonseparable, entangled system, however large is the distance among S_1 and S_2 . In such a case, it is not permissible to consider subsystems S_1 and S_2 individually as

distinct entities that enjoy intertemporal identity. The global character of their behavior precludes any description or any explanation in terms of individual systems, each with its own well-defined state or predetermined physical properties. Only the compound system S , as a whole, is assigned a well-defined (nonseparable) pure state. Therefore, when a compound system such as S is in an entangled state, namely a superposition of pure states of tensor-product forms, *maximal knowledge of the whole system does not allow maximal knowledge of its component parts*, a circumstance with no precedence in classical physics. Erwin Schrödinger, one of the eminent founders of quantum theory, explicitly anticipated this counterintuitive state of affairs by acknowledging the phenomenon of nonseparability as the most characteristic trait of quantum mechanics, the one that enforces its entire departure from classical lines of thought.

The generic phenomenon of quantum nonseparability casts severe doubts on the existence of isolated (sub)systems and the applicability of the notion of atomism, in the sense that the parts of a quantum whole no longer exist as precisely defined individual entities. The nonseparable behavior of an entangled quantum system precludes the possibility of describing its component subsystems in terms of well-defined pure states. In fact, whenever the pure entangled state of a compound system is decomposed in order to represent subsystems, the effect can extend only up to a representation in terms of incompletely specified statistical (reduced) states of those subsystems. Consequently, the state of the whole system cannot be determined by the states of its component parts, this being the case even when these parts occupy distinct regions of space however far apart, because at the quantum domain, in complete contrast to classical physics, it is only the compound state of the whole system that exhaustively specifies the probabilistic entangled correlations among the states of the parts. In this respect, the phenomenon of quantum nonseparability undeniably reveals the holistic character of entangled quantum systems. Quantum mechanics is the first—and right now the only—logically consistent, mathematically formulated, and empirically well-confirmed theory that incorporates as its basic feature that the “whole” is, in a nontrivial way, more than the sum of its “parts,” including their spatio-temporal relations and physical interactions. Contrary to the situation in classical physics, when considering an entangled compound system, “whole” and “parts”

are dynamically related in such a way that their bidirectional reduction is, in principle, impossible.

The Context Dependence of Objects

From a foundational viewpoint of quantum theory, quantum mechanical nonseparability and the sense of quantum holism arising out of it refer to a context-independent, and thus to an observer- or mind-independent, reality. The latter is operationally inaccessible. It pertains to the domain of entangled correlations and quantum superpositions obeying a non-Boolean logical structure. Here, the notion of an object whose aspects may result in intersubjective agreement enjoys no a priori meaning independent of the phenomenon into which it is embedded. In quantum mechanics, in order to be able to speak meaningfully about an object, to obtain any kind of description, or to refer to experimentally accessible facts, the underlying wholeness of nature should be decomposed into interacting but disentangled subsystems, namely, into “measured objects” and “detached observers” (measuring apparatus) with no (or insignificantly) entangled correlations among

them. This subject-object separation is sometimes metaphorically called the Bohr/Heisenberg cut.

The presuppositions of the latter are automatically satisfied in classical physics, in conformity with the separability principle mentioned earlier. In a non-separable theory like quantum mechanics, however, the concept of the Bohr/Heisenberg cut acquires the status of a methodological regulative principle through which access to empirical reality is rendered possible. The innovation of the Bohr/Heisenberg cut, and the associated separation of a quantum object from its environment, is mandatory for the description of measurements. It is, in fact, necessary for the operational account of any directly observable pattern of empirical reality. The very possibility of devising and repeating a controllable experimental procedure presupposes the existence of such a subject-object separation. Without it, the concrete world of material facts and data would be ineligible; it would be conceived in a totally entangled manner. In this sense, a physical system may count as an experimental or a measuring device only if it is not holistically correlated or entangled with the object under measurement.

Consequently, any atomic fact or event that happens is raised at the observational level only in conjunction with the specification of an experimental arrangement—an experimental context that conforms to a Boolean domain of discourse—namely, to a set of observables co-measurable by that context. In other words, there cannot be well-defined events in quantum mechanics unless a specific set of co-measurable observables has been singled out for the system-experimental context whole, because in the quantum domain, one cannot assume, without falling into contradictions, that observed objects enjoy a separate, well-defined identity irrespective of any particular context. One cannot assign, in a consistent manner, definite sharp values to all quantum mechanical observables pertaining to a microscopic object, in particular to pairs of incompatible observables, independently of the measurement context actually specified. In terms of the structural component of quantum theory, this is due to functional relationship constraints that govern the algebra of quantum mechanical observables, as revealed by the Kochen-Specker theorem and its recent investigations. In view of them, it is not possible, not even in principle, to assign to a quantum system noncontextual properties corresponding to all of its observable quantities. In fact, any attempt to simultaneously attribute context-independent, sharp values to all observables of a quantum object forces the quantum statistical distribution of value assignment into the pattern of a classical distribution, thus leading, for instance, to contradictions of the so-called Greenberger-Horne-Zeilinger (GHZ) type.

This state of affairs reflects most clearly the unreliability of the commonsensical possessed values principle of classical physics, according to which the values of physical quantities are regarded as being possessed by an object independent of any measurement context. The classical-realist underpinning of such an assumption is conclusively shown to be incompatible with the structure of the algebra of quantum mechanical observables. In general, well-defined values of quantum observables can be regarded as pertaining to an object of our interest only within a framework involving the experimental conditions. The latter provide the necessary conditions whereby we make meaningful statements that the properties we attribute to quantum objects are part of physical reality. Consequently, the nature of quantum objects is a context-dependent issue, with

the experimental procedure supplying the physical context for their being. Because of the genuinely nonseparable structure of quantum mechanics, a quantum object can produce *no* informational content that may be subjected to experimental testing without the object itself being transformed into a contextual object. In this respect, the introduction of the experimental context operates as a formative factor on the basis of which a quantum object manifests itself. The classical idealization of sharply individuated objects possessing intrinsic properties and having an independent reality of their own breaks down in the quantum domain. Quantum mechanics describes physical reality in a substantially context-dependent manner.

Accordingly, quantum objects cannot be conceived of as things in themselves, as absolute bare particulars of reality, enjoying intrinsic individuality. Instead, they represent carriers of patterns or properties that arise in interaction with their experimental context/environment or, more generally, with the rest of the world; the nature of their existence—in terms of state-property ascription—depends on the context into which they are embedded and on the subsequent abstraction of their entangled correlations with the chosen context of investigation. As Werner Heisenberg has frequently declared, what we observe is not nature itself, but nature exposed to our method of inquiry. Or, to put the same in purely physical terms, because of underlying quantum nonseparability, the world appears as a complex whole. However, once a particular question is put to nature and therefore a given context is specified, the oneness of the whole falls apart into apparent parts. Thus, whereas quantum nonseparability refers to an inner level of reality—a mind-independent reality that is operationally elusive—the introduction of a context is related to the outer level of reality—the contextual or empirical reality that results as an abstraction in the human perception through deliberate negligence of the all-pervasive entangled correlations between observed objects and their environments. The latter abstraction is dictated by the fact that, within the framework of quantum mechanics, it is solely the process of disentanglement that generates the perceptible separability and determinateness of the objects of empirical reality by means of an experimental intervention that suppresses (or sufficiently minimizes) the factually existing entangled correlations of the object concerned with its environment. It is then justified to

say that the fulfillment of the disentanglement procedure provides a level of description to which one can associate a separable, albeit contextual, concept of reality whose elements are commonly experienced as distinct, well-localized objects having determinate properties.

Active Scientific Realism

The context dependence of quantum objects does not contradict a realistic view of the world as usually assumed. Scientific realism and quantum nonseparability are not incompatible, but the relationship between them points to the abandonment of the classical conception of physical reality and its traditional metaphysical presuppositions, most notably atomism and strict ontological reductionism. Because of the substantially context-dependent description of reality suggested by quantum mechanics, one ought to acknowledge that the patterns of nature emerge and become intelligible through an active participation of the knowing subject that, by itself, is not and cannot be perspective-independent. In this sense, the conceptualization of the nature of reality, as arising out of our most basic physical theory, calls for a kind of contextual realism that we call *active scientific realism*.

It is active because it indicates the contribution of rational thought to experience; it acknowledges the *participatory* role of the knowing subject in providing the context of discourse; as previously argued, the identification of a specific pattern as an object depends on the process of knowledge, on the abstraction or suppression of the entangled correlations between the object concerned and its external environment, and this may be done in different, physically nonisomorphic ways depending on the chosen context of investigation.

It is realism because, given a context, concrete objects (structures of reality) have well-defined properties independent of our knowledge of them. According to the conception of active scientific realism, the experienced or empirical reality is a functional category. Functional to the engaging role of the knowing subject, so that the empirical reality is perceived as not something given a priori, a “ready-made” truth dictated allegedly by an external point of reference, but as something affected by the subject’s action. Whereas in the old classical paradigm, scientific descriptions were regarded as being independent of the knowing subject and the process of knowledge,

in the new quantum paradigm, epistemology, namely, the understanding of the process of knowing—has to be explicitly included in the description of natural phenomena. In other words, epistemology inevitably becomes now an integral part of the theory. The nonseparable structure of quantum theory, the experimentally well-confirmed holistic features arising out of it, and the subsequent context-dependent description of physical reality conflict with the rather comfortable view that the world’s contents are knowable in an intrinsic and absolute sense. Within the domain of quantum mechanics, knowledge of reality in itself—the real such as it truly is, independent of us—is impossible in principle.

Independent Reality and Contemporary Physics

It should be underlined, however, that even if our knowledge will never be knowledge of reality itself, independent of the way it is contextualized, there is no reason, from the viewpoint of natural philosophy, to reject as meaningless or redundant the notion of a mind-independent reality. On the contrary, we consider the latter as unassailable in any scientific discourse; we amply recognize its existence as being logically *prior* to experience and knowledge; we acknowledge its externality to the mind structure as being responsible for resisting human attempts in organizing and conceptually representing experience. But, significantly, in the quantum domain, the nature of this independent reality is left unspecified. Because of the generalized phenomenon of quantum nonseparability, we must conceive of independent reality as a highly entangled whole with the consequence that it is impossible to conceive of parts of this whole as individual entities, enjoying autonomous existence, each with its own well-defined state. Neither reality considered as a whole could be comprehended as the sum of its parts, because the whole, according to considerations mentioned earlier, cannot be reduced to its constituent parts in conjunction with the spatiotemporal relations among the parts. Therefore, quantum nonseparability seems to pose a novel limit on the ability of scientific cognizance in revealing the actual character of independent reality itself. Any detailed description of the latter necessarily results in irretrievable loss of information by dissecting the otherwise undissectable. From a fundamental viewpoint of quantum mechanics, any discussion concerning the

nature of this indivisible whole is necessarily of an ontological, metaphysical kind, the only confirmatory element about it being the network of entangled interrelations that connect its events. In this respect, it can safely be asserted that reality thought of as a whole is not scientifically completely knowable, or, at best, in D'Espagnat's expression, it is veiled. Hence, our knowledge claims to reality can be only partial, not total or complete, extending up to the structural features of reality that are approachable by the penetrating power of the theory itself and its future development.

The Role of Mind in the Physical World

The term *reality* in the quantum realm cannot be considered to be determined by what physical objects really are in themselves. As already noted, this state of affairs is intimately associated with the fact that, in contrast to classical physics, values of quantum mechanical quantities cannot be attributed to a quantum object as intrinsic properties. The assigned values cannot be said to belong to the observed object alone regardless of the overall experimental context that is relevant in any particular situation. Hence, the quantum mechanical framework seems to allow only a detailed description of reality that is co-determined by the specification of a measurement context. What contemporary physics, especially quantum mechanics, can be expected to describe is not how mind-independent reality is, as classical physics may permit one to presume. Within the domain of quantum mechanics, the role of the knowing/intentional subject, that is, the experimenter/observer, is indelibly marked. According to the physico-mathematical structure of standard quantum mechanics, the mere freedom, on the part of the experimenter, to select the experimental context, to choose the question asked of nature and specify the timing of its asking, allows him or her to exert an indelible influence on a quantum system that is not, in general, fixed by the prior part of the physical world alone. Thus, by way of a generalized example, if A, B, and C represent observables (physical quantities) of the same quantum system, so that the corresponding Operator A commutes with Operators B and C ($[A, B] = 0 = [A, C]$), but not, however, the Operators B and C with each other ($[B, C] \neq 0$), then the result of a measurement of A *depends* on whether the experimenter had previously subjected the system in a measurement of the observable B, a

measurement of the observable C, or none of them. Hence, the value of the observable A depends upon the set of mutually commuting observables with which one may consider it; that is, the value of A depends upon the set of measurements one may select to perform. In other words, the value of the observable A cannot be thought of as pre-fixed, as being independent of the experimental context actually chosen. This may simply be viewed as a lemma of the Kochen and Specker theorem noted earlier, whereas analogous, still more vivid statements to this consequence can be made through recent investigations of established effects in quantum theory such as the quantum Zeno effect and the so-called delayed choice experiments.

Thus, quantum mechanics undeniably reveals a sense in which the knowing subject participates in bringing reality into being. Indeed, the conception of active scientific realism—put forward here as an interpretive, regulative hypothesis to physical science—attempts to incorporate the human factor into our understanding of reality within which human knowledge forms an indispensable part. It aims at appropriately expressing within physics the sense in which this is a “participatory universe,” just to recall John Wheeler’s phrase. It acknowledges the subject-object inherent engagement that is built into quantum theory by appropriately integrating the subjective human increments into an objectively existing physical reality. There is an ever-growing recognition that the Cartesian ideal of an absolute dichotomy between the human mind and the external world, allowing no intermediate medium, is fundamentally flawed. It leads to an alleged construction of decontaminated-by-human-qualities knowledge—a supposedly perspective-free view of the world—that is insufficient to really understand reality. In contradistinction, active scientific realism attempts to convey that the actual relation of the knowing subject to a world is not of absolute dichotomy, nor of independence or externality, but of active participancy. Thus, in coming to know the physical world, we also come to know ourselves as knowers and consequently understand how our perspective affects or contributes to our conceptualization about the world, because in contemporary physics, such an *effect* is unavoidable. And conversely, by knowing how we contribute to the knowledge claims about the world, we identify more securely the informational content the world itself contributes. In this view, human

subjectivity and scientific objectivity, within the respective limits of their appropriateness, are no longer contraries; they are jointly achieved.

Viewing the World From Within

In light of the preceding considerations, the common philosophical assumption concerning the feasibility of a panoptical, Archimedean point of view is rendered illusory in quantum mechanics. In contrast to an immutable and universal “view from nowhere” of the classical paradigm, quantum mechanics acknowledges in an essential way a perspectival character of knowledge. Although possible in classical physics, in quantum mechanics, we can no longer display the whole of nature in one view. Access to the non-Boolean quantum world is gained only by adopting a particular Boolean perspective, by specifying a certain Boolean context that breaks the wholeness (the underlying nonseparability) of nature. Consequently, the description and communication of results of experiments in relation to the non-Boolean quantum world presuppose the impossibility of a perspective-independent account, because one must, at the outset, single out an experimental context (determined by a set of co-measurable observables for the context-quantum system whole) and in terms of which the definite result of a measurement can be realized.

Be sure that there is only one external reality, but every description of it presupposes—according to quantum mechanics—the adoption of a particular point of view. There is no such thing as a “from nowhere” perspective or a universal viewpoint. A complete knowledge of the world as a whole would have to provide an explanation of the perception process or the pattern recognition mechanisms of the knowing subject, because this is part of the world. It would have to include within a hypothetically posited ultimate theory an explanation of the conditions for observation, description, and communication to which we ourselves, as cognizant subjects, are already subjected. We cannot transcend them. This would be like attempting to produce a map of the globe that contained itself as an element. The usage of this metaphor is meant to convey the conceptually deep fact—reminiscent of Gödel’s famous undecidability theorem for axiom-system in mathematics—that a logically consistent theory cannot generally describe its universe as its own object. In particular, the scientific language of our hypothetical universal ultimate

theory would have to be semantically closed, and hence engender antinomies or paradoxes especially in relation to self-referential descriptions, as in the case of von Neumann’s account of quantum measurement that leads to an infinite regress of observing observers.

Be that as it may, the assumption of a “view from nowhere” appeared realizable prior to quantum mechanics, because in classical physics, the validity of separability and unrestricted causality led to the purely reductionist presumption that one could consistently analyze a compound system into parts and consequently deduce the nature of the whole from its parts. Because the part could be treated as a closed system separate from the whole, the whole could ultimately be described—by applying the conservation laws of energy, momentum, and angular momentum as the sum of its parts and their physical interactions, and hence the knowing subject would achieve its knowledge of physical reality from the outside of physical systems.

In the quantum theoretical framework, that picture is no longer valid. Because of the genuinely nonseparable structure of quantum mechanics, any compound entangled system is characterized by properties that, in a clearly specifiable sense, refer to the whole system but are not reducible to, implied by, or derived from any combination of the local properties of its parts. Hence, the legendary notion of the classical paradigm that wholes are completely describable or explicable in terms of their constituent parts is flagrantly violated. In quantum mechanics, as already adumbrated, the whole is simply not equivalent or reducible to the sum of its parts, including the spatio-temporal relations and physical interactions among the parts.

When all is said and done, the present situation in physics suggests that the natural scientist as a conscious being may operate within a mild form of the reductionist paradigm in trying to analyze complex objects in terms of parts, with the absolute certainty, however, that during the process, the nature of the whole will not be disclosed. The value of the reductionistic concept as a working hypothesis or as a methodological tool of analysis and research is not jeopardized at this point, but *ontologically*, it can no longer be regarded as a true code of the actual character of the physical world and its contents. Quantum mechanical nonseparability strongly suggests that the functioning of the physical world cannot just be

reduced to that of its constituents, thought of as a collection of interacting but separately existing localized objects. Any coherent conceptualization of the physical world that is compatible with the predictions of quantum mechanics requires us to view the world as a complex network of relations or processes among events that may interchange or overlap or coalesce and thereby determine the texture of a unified dynamic whole. Although the latter can hardly be fully knowable, an enlightenment of its actual character may be given by the penetrating power of the theory itself and its future development. In this respect, it is rather safe to conjecture that the conception of quantum nonseparability will be an integral part of the next conceptual revolution in physics and may even be used as a regulative constructive hypothesis guiding the search for our deeper understanding of nature.

The Navajo have an amazingly rich history and cultural background. One of the best known Native American groups because of their weaving and silver jewelry, it is difficult to adequately paint their picture in a condensed historical portrait. The Navajo, also known as Dine (or “the people”), are relative newcomers in the American Southwest. More than 1,000 years ago (ca. AD 1000), the Navajo migrated south from northern Canada to the American Southwest.

When they arrived, this region was already occupied by ancestral Puebloan populations. The ancestral Puebloans lived in settled agricultural communities, a way of life that conflicted with the nomadic hunting and gathering practices of the Navajo. Prior to their arrival in the Southwest, the Navajo primarily hunted animals such as deer and buffalo, and gathered wild plant foods. Although hunting and raiding were formerly important in Navajo economy, they are essentially obsolete today. Their cultural adaptability is compelling, as is their ability to remain relatively unchanged; maintaining their original lifeway was a struggle for the Navajo as they negotiated relationships with their new Puebloan neighbors and strained under the arrival of Europeans.

Adaptation and Survival

The Long Walk

In 1860, the Navajo attacked Fort Defiance, a post that had been established in their territory. As a result, the U.S. military planned the evacuation of the Navajo homeland, and forced resettlement of Navajo and Apaches at the Bosque Redondo (Fort Sumner) in eastern New Mexico, where they were to be taught how to become farmers. The plan, and subsequent “long walk” (of more than 270 miles), were carried out between 1863 and 1864; more than 8,000 Native Americans were led to Fort Sumner. The attempt at forced acculturation at Fort Sumner was a disaster; the land was unsuitable for farming and sheep herding, and there were inadequate supplies of water and fuel. Finally, in 1867, those held captive at Fort Sumner were allowed to leave, and a reservation that was created for them in 1868 contained less than 10% of the land they had originally used.

Despite their status as newcomers in this region and the reduction in their territory, however, the Navajo currently comprise one of the largest Native American tribes in North America, numbering around 200,000 members on a 17 million acre reservation that extends from southern Utah to the northern portions of Arizona and New Mexico. Hoover stated that “the solid block of Navajo reservation area included 25,000 square miles or 16,000,000 acres. Nine states of the United States are smaller. The real Navajo country, the country occupied chiefly by Navajo, comes nearer to 28,000 square miles, an area larger than Ireland.” The land that was designated to the Navajo was land that was considered of no real

use or benefit. Some parts are considered desert, and other parts have intermittent trees. Over the subsequent years, this reservation land has been greatly expanded, removed, renegotiated, exchanged, and disputed, but the region of the land has generally remained constant.

A Changing Way of Life

Following the failed experiment at Bosque Redondo, the Navajo way of life changed significantly. Continued contact with Pueblo culture certainly affected that change. Although the Navajo continued to supplement their diet with foraging and minimal hunting, reduced territory greatly affected their ability to continue to survive as hunter-gatherers. Sheep and goat herding increased in importance. Goat herds provided sources of meat, milk, and cheese, whereas the maintenance

of sheep herds provided meat and the ever-important wool used for weaving blankets and garments. Some families also kept pigs and chickens to use for other food sources, as well as horses for transportation and for an additional meat source. Minimal farming of items such as corn, squash, beans, and melons was also a small aspect of changing Navajo subsistence strategies, but sheepherding eventually became the primary focus of subsistence strategies.

Although herding still continues, much of the economic survival of the Navajo today depends upon artistic traditions such as silversmithing, especially with turquoise; hand-woven blankets, rugs, and garments; and pottery. The Navajo learned silverworking from the Spanish and pottery-making from their Puebloan neighbors, and both of these crafts are certainly coveted by collectors. signatures of their culture. These crafts are typically the art of women, and even though weaving provides significant economic assistance to the Navajo, its significance is so much more than economic. The Navajo have a history of myths that continues to inspire them in daily life; weaving is one aspect of that inspiration. As McPerson noted, “The knowledge associated with it originated in the times of the Myths, when Spiderwoman taught the first Navajos this trade.”

Spider Woman instructed the Navajo women how to weave on a loom which Spider Man told them how to make. The crosspoles were made of sky and earth cords, the warp sticks of sun rays, the healds of rock crystal and sheet lightning. The batten was a sun halo, white shell made the comb. There were four spindles; one a stick of zigzag lightning with a whorl

of cannel coal, one a stick of flash lightning with a whorl of turquoise; a third had a stick of sheet lightning with a whorl of abalone; a rain streamer formed the stick of the fourth, and its whorl was with the shell. (Navajo Legend)

The Hogan

Stephen Jett noted that “despite modifications during the several centuries that the Navajo (Dine) have inhabited the Southwest, basic Navajo settlement practices derive from those of the Navajo Northern Canadian Athapaskan hunting and fishing forebears who migrated to the Southwest.” A distinctive feature of Navajo material culture is the hogan, a traditional domed dwelling that today is used almost exclusively for ceremonial purposes. Hogans are generally one-room structures made of wooden poles, tree bark, and mud with doorways always facing east. The entrance faces the rising sun because the hogan is designed to symbolize the security of shimah (the Navajo mother or the earth). On reservation lands, hogans are often still used as residential structures, but their use for this purpose is decreasing. These domed, mud structures can also often be seen in the back yards of city Navajo, although plywood and lumber versions are becoming common in such locales. Despite the persistence of the hogan as a ceremonial structure, Navajo spirituality has changed over the years.

Spirituality

A distinctive feature of Navajo religion is the sand paintings created during a ritual in order to ascertain the cause and cure of a malady that may be spiritual, physical, or emotional. The sand paintings are filled with a religious symbolism that is indicative of the nature of Navajo spirituality today. They frequently feature images or embodiments of the First Man and First Woman. Interestingly, the Navajo origin myths embodied in these sand paintings share much with the Christian story of creation. It is such similarities that allow for spirituality that blends Christian beliefs with traditional ones. “Most native Americans believe the universe has some kind of Almighty, a spiritual force that is the source of all life. The sun is viewed as the power of the formless and exists in the universe. The sun is viewed as the power of the Almighty.” It is said that the Indians do not worship the sun but the symbol for which it stands. They look at the land on which they live in the same way; they often feel that the land has some kind of life and power, and that it is

a deity in itself. McPherson said that “the Navajo perception of their land was rooted in their belief that it was imbued with power and religious significance. The earth was a living breathing entity that nourished, blessed, healed and protected its people.” Rather than existing in conflict with, such traditional ceremonialism exists side by side with the practice of Christianity. It is this side-by-side existence that allows for the malleability of the Navajo culture.

The Present Day

The Navajo contribution during World War II continues to demonstrate the flexibility of the Navajo and the richness of their culture. Navajo soldiers served as “Code Talkers” during this war. Their role was in secret communications because the language of the Navajo was recognized as an impermeable military code. The Navajo language was so complex that with every syllable change, the meaning of the words changed. This made the Navajo a great asset to the United States. During this war, they fought in battles as well as used their language to code secret messages to other parts of the Army. Despite their ill fate during the early years of European colonization, the Navajo took an active part in World War II. They volunteered for service and fought overseas battles, while the women worked for the Red Cross on the Navajo reservation. These brave men and women have only just been recognized by the United States. In July 2001, more than half a century after the end of the war, the original 29 Navajo Code Talkers who developed the code were given the Gold Congressional Medal of Honor.

Following World War II, cultural changes emerged in the Navajo nation. In modern times, although sheep and goat herding are still carried out and crafts are still produced for sale to tourists, much economic revenue on the Navajo reservation is generated from the extraction and processing of oil, coal, and timber. The importance of these commodities and the amount of revenue they generated led to the formal creation of a self-governed Navajo tribal council. The Navajo gained authority over education, health services, cultural resources, and other important aspects of culture as they created a new infrastructure. Today, the Navajo Nation Council has grown into the largest and most sophisticated American Indian government in the United States.

The story of the Navajo is one of strength and perseverance. Once strangers in a new land, they have

shown that through adversity, they are survivors, accepting change yet maintaining key traditional values. The continuing success of the Navajo nation is certain because of this persistence.

NAZCA CULTURE

Nazca culture, also known as Nasca, flourished in southern Peru during the period around A.D. 1 to A.D. 700. The Nazca culture emerged in distinct stages: Early, Middle, and Late, with a Classic period between A.D. 250 and A.D. 750, the time during which the Nazca lines were constructed. From studies of ceramic designs in the region, archaeologists assert that Nazca culture appears to have developed out of the Paracas culture before it. Additional archaeological evidence shows that after A.D. 900, the Nazca apparently fell under the Tiahuanaco culture influence until the Inca eventually conquered the entire region in the 15th century.

Nazca agricultural settlements were located in the Nazca, Pisco, and Ica River valleys on the desert coast.

Nazca farming was possible on the desert because of the irrigation systems they constructed to bring water down from the mountains. In addition to their crops and animal husbandry, the Nazca relied on hunting and fishing. In the 1930s, aerial exploration of the desert land surrounding the Palpa Valley revealed a remarkable network of lines and trapezoids. The lines formed giant animals, flowers, plants, and human figures. Through radiocarbon dating and the resemblance of the geoglyphs to pottery designs, archaeologists were able to identify the lines as Nazcan. Anthropologists further theorize that these figures were built to be seen by giant condors, which the Nazca people believed brought the rains to their desert croplands. The lines are also thought to be related to Nazca astronomy and to collectively form a giant calendar. Some 300 figures, well preserved, cover nearly 400 square miles of the desert pampa sand, where there is little rain or wind to erode the ancient past.

Nazca artisans excelled in their production of beautiful ceramics and textiles. Highly polished, expertly designed, and polychrome painted, the pottery of the Nazca is unlike that of any other Peruvian culture known. Nazca textiles show multitudes of weaving techniques and exemplary skills in dyeing with several shades of the same color. Archeological excavation reveals that both coastal cotton and highland alpaca wool were used in Nazca textiles. The Nazca also traded with other cultures in the region.

Although some theorists argue that the Nazca were a violent and warlike pre-state people, no crucial evidence has been found to support this claim. The Nazca engaged in regional warfare only to protect

their territory. Long before the encroachment of Europeans, the Nazca were assimilated into other cultures. Their lives lived on, however, in local legends and lines until archeologists reconstructed their culture and its role in the development of later and larger empires. The Nazca are now understood to have contributed greatly to the development of subsequent state societies through (a) complex irrigation systems, (b) weaving technologies from cotton grown on the coast and alpaca raised in the mountains, and (c) the production of pottery for food storage and trade.

NEANDERTAL BURIALS

Although it is possible that early humans buried their dead for purely hygienic reasons or to discourage scavengers, many anthropologists view intentional burial as a kind of symbolic behavior. Some have even suggested that it represents the earliest evidence of religion. Therefore, it is understandable that the subject of Neandertal burials is a controversial one. Although not always explicit, this controversy is linked to different perceptions regarding Neandertal cognition and intelligence. It is also rooted in the debate over modern human origins and the “humanness” of Neandertals.

In general, opinions among anthropologists fall within three camps. First, some anthropologists believe that all evidence for Neandertal burials can be explained by natural processes. They claim there is no scientifically sound evidence that Neandertals buried their dead. Second, other anthropologists accept that Neandertals may have buried their dead occasionally and sporadically. They believe the motives behind Neandertal burials were different from those of modern human burials (for example, practical vs. symbolic). Finally, still other anthropologists believe that the characteristics of, and motivation behind,

Neandertal and anatomically modern human burials were the same, suggesting that the cognitive capacities of the two groups were similar, if not identical.

Much of the disagreement over whether or not Neandertals buried their dead is linked to different standards used to identify a burial. For some, the criteria may be quite simple. For example, good preservation may be enough for some anthropologists to conclude that an individual was intentionally buried. Others require more rigorous criteria, such as the position of the body (flexed), evidence of a burial pit, grave markers, and/or inclusion of grave goods. Although not the most popular view, some anthropologists claim that one must completely disprove the role of natural processes in order to properly interpret a skeleton as a burial.

More Neandertal sites lack rather than possess evidence of intentional burial. Generally speaking, Neandertal burials are simpler than those of later Upper Paleolithic humans. When present, the burial pits associated with Neandertal skeletons are shallow, and some clearly have a natural origin. Only about half of the Neandertal burials include possible grave goods (for example, stone tools, animal bones, and/or pigment). Because these grave goods are not very different from the items found in the surrounding deposit, it is difficult to rule out the possibility that the items were accidentally included in the grave fill. This contrasts sharply with graves associated with later Upper Paleolithic European burials, which often contain large numbers of art objects and are clearly contained in a pit of human manufacture. The most convincing evidence that Neandertals occasionally buried their dead is that many of the skeletons, especially those of juveniles and infants, are well preserved.

If we use the somewhat looser criteria of most anthropologists, there are approximately 20 Neandertal sites for which there is probable or certain evidence for one or more intentional burials. Some of the better known sites are discussed below.

In 1908, at the site of La Chapelle-aux-Saints, France, a Neandertal skeleton was excavated from a large, roughly rectangular depression. The “old man from La Chapelle” was the first Neandertal skeleton to be interpreted as deliberate burial. The skeleton was well preserved and nearly complete, found lying on its back in a tightly flexed position. Animal bones may have been included as grave goods.

Not long after (1908 and 1914), two individuals, a young adult and an infant, were excavated from another

French site called Le Moustier. Both individuals are said to have been intentionally buried. Le Moustier 1, the young adult, is hypothesized to have been laid on a pillow of stone artifacts. Le Moustier 2, the nearly complete skeleton of an infant, was associated with a shallow pit, but its excellent preservation is the strongest evidence that it was intentionally buried.

Between 1909 and 1920, two nearly complete and five fragmentary Neandertal skeletons were excavated at Le Ferrassie, France. Although La Ferrassie 1 (an adult) was not associated with a grave, it has been interpreted as a burial based on its flexed position and the presence of three limestone blocks near its head and shoulders. A year later, a second adult (La Ferrassie 2) was found only a half-meter from the first. La Ferrassie 2 was positioned head-to-head with La Ferrassie 1, and evidence suggests that both were buried at about the same time. As excavations continued, two immature individuals were discovered. La Ferrassie 3 is the partial skeleton of a 10-year-old. La Ferrassie 4 is the skeleton of a newborn infant. Both were discovered in shallow pits. Their association with burial pits and their good preservation has been considered evidence of intentional burial. La Ferrassie 5 was found beneath one of nine meter-sized, cone-shaped mounds that have been assumed to be ritually placed. La Ferrassie 6 consists of the partial skeleton of a 3-year-old child. The skeleton was discovered in a very large pit. Some anthropologists believe that the cranium—which was found 1.25 m away from the body—had been ritually removed.

Excavated in 1939, the burial at Grotta Guatarri, Italy, consisted of an irregular ring of rocks surrounding a Neandertal skull that was missing the base of the skull. The rock ring has been interpreted as being ritually placed. The missing skull base has been interpreted as evidence that Neandertals extracted the brain as part of a cannibalistic ritual. However, the skull lacks evidence of human butchering, and it is possible that carnivores, rather than humans, were responsible for the damage. In addition, some have questioned the placement of the skull inside the ring, because it had been moved and replaced before it was seen by scientists.

One of the most famous Neandertal burials comes from Shanidar Cave in Kurdistan, Iraq. Excavated in the 1950s and 1960s, most of the individuals at Shanidar are presumed to be burials based on the position of their bodies, their preservation, or their association with alleged grave goods. Of these,

Shanidar 4 (the flower burial) is the best known. The discovery of a substantial quantity of flower pollen in the soil surrounding the individual led to the conclusion that the individual was buried ceremoniously with flowers. Skeptics of this interpretation point out that the accumulation of the flower pollen could be the result of rodent activity rather than mortuary ritual.

Another possible Neandertal burial was found in 1938 at a site called Teshik Tash in Uzbekistan. Teshik Tash consists of a partial skeleton of a 9-year-old Neandertal child. It has been hypothesized that the individual was buried in a shallow grave and subsequently surrounded by ritually placed goat horns. Skeptics, however, claim that the child's bones had been disturbed by scavengers, which suggests that its (natural) burial occurred some time after its death. The evidence for a grave—intentional placement of the goat horns—has also been questioned by some.

Although not uncritically accepted, the hypothesis that Neandertals at least occasionally buried their dead appears to be supported. Exactly what this means—in terms of religion, symbolism, and ultimately the humanness of Neandertals—probably will not be resolved any time in the near future.

NEANDERTAL EVIDENCE

Neandertals made their appearance midway through the 19th century, at a critical moment in intellectual history, when old but comfortable ideas about the human past were beginning to fall apart and new but shocking ideas (such as evolution) were coming in. The old ideas did not explain Neandertals. The new ones, which could, were generally poorly understood. Therefore, no one was prepared for the sight of a

primitive-looking skeleton in the human closet. But when such a skeleton appeared in Germany in 1856, in the Neander Valley (or Neandertal in old German), it brought on a sense of denial to its connection to *Homo sapiens*. The workmen, who had blasted open a small cave in their search for limestone, never realized the significance of their find.

Neandertals and present-day *Homo sapiens*, although they have many similarities, have significant anatomical differences. Neandertals lived 100,000 to 35,000 years ago and are considered by many to be a direct relative of modern humans. Over the past two decades, new analyses of fossil remains and sophisticated models have shown greater anatomical differences between humans and the Neandertals. The Neandertal's bone and ligament size are much greater and thicker than ours. Their arm, leg, shoulder, and even finger bones were very thick and durable to deal with their harsh conditions. These findings have also led to new conclusions concerning

the behavior of Neandertals, such as their ability to care for the sick and weak, and also the possibility of aggression within the species itself, both of which are modern human qualities. Neandertal's place in human evolution has been both strengthened and weakened by this relatively new information.

All muscles that go from the shoulder blade to the upper end of the arm demonstrate massive development in the Neandertals, particularly the muscles responsible for powerful downward movements of the arm and muscles that stabilized vigorous shoulder movements. Because the skeleton must be capable of supporting increased levels of stress within its environment that are frequently several times as great as body weight, the enlarged attachments for muscles and ligaments are associated with leg bone shafts that have been reinforced. The shafts of all of the arm and leg bones are tubular structures that have to absorb stress from bending and twisting without fracturing. The Neandertal's ligament surface area was also greater than a modern human's, therefore effectively reducing the force per square unit of pressure on its joints and cartilage to deal with increased levels of stress.

Between 1953 and 1960, anthropologist Ralph Solecki of Columbia University excavated a series of partial skeletons from Shanidar Cave in northern Iraq. From studies on these skeletons by Dale Stewart, an anthropologist at the Smithsonian Institute, and Erik Trinkhaus, they discovered that several of the skeletons showed signs of trauma during their life. The left ninth rib of the skeleton at Shanidar 3 showed a partially healed wound by a sharp object. The position of the wound on the rib, the angle of incision, and the cleanliness of the cut make it unlikely that the injury was inflicted accidentally. It appears exactly like a wound inflicted by a right-handed adversary in face-to-face combat. Many finds from the Neander Valley, La Chapelle, and La Quina have all shown signs of trauma, but the interesting fact lies in that, despite these traumas, the Shanidars did not die until they were somewhere between 40 and 60 years old, providing evidence that individuals were taken care of long after their economic usefulness to the social group ceased.

Neandertals, therefore, are anatomically quite different from modern humans, but behaviorally, they show many similarities. Neandertal limbs and ligaments were tougher, thicker, and stronger than our own to deal with the harsher conditions they faced, such as hunting and defense from predators. Their arms, fingers, and legs were able to handle increased

levels of stress, showing they led very active lives. Behaviorally, however, a Neandertal was quite similar to *Homo sapiens*. Signs of trauma, perhaps caused by other Neandertals, were found at Shanidar Cave, revealing aggression much like that of our own species today. The fact that some of the Neandertals lived to a relatively old age, despite these traumas, details their ability to care for the injured or weak long after their usefulness to the group ended, just as we do today. Neandertals are a key link in human evolution, and many of our modern traits can be discovered in this species. Perhaps with time, we will discover that we have even more similarities with them.

NEANDERTAL SITES

Neandertal sites are found throughout most of Europe, in Western Asia, and in parts of Central Asia. In the early and mid-1900s, anthropologists Franz Weidenreich and Aleš Hrdlička proposed that all modern humans went through a Neandertal stage of evolution. Under this model, all Middle Pleistocene hominid fossils that were morphologically intermediate between *Homo erectus* and anatomically modern humans were referred to as Neandertals. Thus, literature in the mid- and later 20th century may refer to Asian or African Neandertals, but this has generally fallen out of practice.

Neandertals are often thought of as cave dwellers because most sites are discovered in rock shelters and caves. However, it is important to remember that certain biases may be partially responsible for the distribution of Neandertal sites on the landscape. For

example, there is a bias toward finding fossils in caves and rock shelters where they are better protected and more likely to be preserved. Moreover, the number of sites discovered in Europe is at least partially a result of European historical interest in (and thus interest in finding evidence for) human evolution.

The first Neandertal recognized as such was found at Feldhofer Cave in the Neander Valley near Dusseldorf, Germany. It is for this site that Neandertals were named (valley = *Tal* in German). Feldhofer 1 was discovered in 1856, 3 years before Charles Darwin published *On the Origin of Species*. Without any evolutionary framework in which to interpret the fossils, they were first believed by Johann Fuhlrott to represent an extinct human race that was replaced by the ancestors of modern Germans. In contrast, the famous biologist Rudolf Virchow believed the Feldhofer specimen was a pathological modern human. Still others believed the bones were the remains of a Cossack from the Napoleon Wars. The original fossils from Feldhofer Cave included a skull cap and a partial postcranial skeleton. Excavations at Feldhofer Cave have been recently reopened, and additional remains of Feldhofer 1, together with those of other individuals, have been recovered.

Although Neandertals were named for the Feldhofer site, the Feldhofer specimen was not the first Neandertal discovered. The cranium of a Neandertal child (Engis 2) had been discovered near Engis Village, Belgium, in 1829. Likewise, the cranium of an adult Neandertal from Forbes Quarry, Gibraltar, had been reported in 1848. However, as with the Feldhofer specimens, their evolutionary significance was not appreciated until much later.

The fossil from the site of La Chapelle-aux-Saints, France (discovered in 1908), has played an important role in how we view Neandertals. The Neandertal image—that of a hunched over, bent-kneed, awkward-looking caveman—can be traced to Marcellin Boule’s inaccurate reconstruction of this fossil published between 1911 and 1913. Boule believed that Neandertals played no part in human evolution. Thus, it is no surprise that he would describe Neandertals as intellectually inferior despite this specimen’s cranial capacity of more than 1600 cc (well above the modern human average of 1450 cc). However inaccurate, this negative image has been difficult for Neandertals to shed. We now know that La Chapelle-aux-Saints (“Old Man from La Chapelle”) was a severely arthritic old man whose bent posture

was the result of the disease. As such, it was not representative of Neandertals as a whole.

Since these early discoveries, thousands of Neandertal sites have been discovered. Not all Neandertal sites are associated with fossils, however. In fact, most have been identified on the basis of Middle Paleolithic or Mousterian tools. Indisputable Neandertal remains are currently known from more than 80 sites dating to between 130,000 and 28,000 BP. They span Europe and parts of Western and Central Asia.

Among the most ancient Neandertal sites are Krapina, Croatia (130,000 BP), and Saccopastore, Italy (120,000 BP). The Krapina remains were excavated between 1899 and 1905. They represent one of the largest collections of Neandertal fossils, with close to 400 cranial and mandibular fragments and nearly 200 teeth. The Saccopastore individuals were excavated in 1929 (Saccopastore 1) and in 1935 (Saccopastore 2). Saccopastore 1 is a nearly complete adult cranium and Saccopastore 2 is a less complete adult cranium.

The two most recent Neandertal sites comprise the fossils from Zafarraya, Spain (27,000 BP), and Mezmaiskaya in the northern Caucasus, Russia (29,000 BP). Excavated in the early 1980s, the fossils at Zafarraya play a pivotal role in the hypothesis that the Iberian Peninsula was a refugium for late surviving Neandertals. The individuals at Mezmaiskaya are also quite recent. Excavated between 1987 and 1997, the specimen that has received the most attention is an infant dating to 29,000 BP. Mitochondrial DNA extracted from the infant shows that it is very similar to DNA extracted from other (geologically older) Neandertals, indicating little genetic change in the species over time.

Outside Europe, excavations above the Wadi Amud, Israel, took place in the 1960s and were resumed again in the 1990s. Two important fossils are known from this site. Amud 1 is the tallest known Neandertal (1.8 m or 5'8") with the largest cranial capacity (1740 cc). Amud 7 is a 10-month-old infant, which demonstrates that distinctive Neandertal cranial morphology is present even in very young individuals. Both date to approximately 40,000 to 50,000 BP and are presumed to be burials. Excavations in Tabun Cave, Israel, took place between 1969 and 1971. The fossils from Tabun may be as old as 120,000 years. The Neandertal fossils from Shanidar, Iraq, excavated in the 1950s and 1960s, date to 70,000 BP. The site is notable for (among other things) the number of skeletons discovered (seven) and for their alleged status as Neandertal burials, including the famous "flower burial" (Shanidar 4).

Further east, in Uzbekistan, a site named Teshik-Tash (70,000 BP) is the easternmost Neandertal site known to date. Here, a 9-year-old child was discovered in 1938. It is frequently cited as an example of Neandertal burial because of its association with presumed ritual placement of goat horns.

Finally, one of the most recently discovered Neandertal fossils comes from a site not far from Teshik-Tash. The fossils from Obi Rakhmat (published in 2004) consist of cranial fragments and teeth from two individuals. The analysis of these fossils is not complete, but initial results suggest that they are somewhat different from those Neandertals found in western Europe. This indicates that geographic variation existed among Neandertals, just as it does among modern humans today.

From the discovery of the first Neandertal, our image and interpretation of these enigmatic humans has been changing. Excavations of Neandertal sites, both old and new, are ongoing. There is no doubt that new fossils will continue to come to light and shape our understanding of Neandertals for decades to come.

NEANDERTALS

Neandertals were a morphologically distinct human population that existed in Europe and Western Asia from about 200,000 to 30,000 BP (before present). The first recognized Neandertal discovery occurred in

1856, when the remains of part of the skeleton of one individual was discovered in the Feldhofer grotto, in Neander Valley, near Düsseldorf, Germany. This material was recovered by quarry workers and set aside for a local teacher and amateur naturalist, Johann Karl Fuhlrott. Fuhlrott suspected that the find might be important and took the material to anatomist Hermann Schaaffhausen. The material was jointly announced in 1857, two years before Darwin published *The Origin of Species*. The term *Neandertal* is derived from the species designation *Homo Neandertalensis*, given to the material by William King in an 1863 meeting of the British Association. Feldhofer was the first recognized Neandertal discovery, but in later years, other earlier finds were placed within the Neandertal clade, including the Engis child discovered in Belgium in 1829, and the Forbes Quarry material discovered in Gibraltar in 1848.

Early History

Early interpretations of Neandertals were marred by misrepresentation and misdiagnoses of the nature of the anatomical features seen in the material. In the early years after the Feldhofer discovery, many researchers did not even recognize the antiquity of the material. For example, in 1872, Rudolf Virchow published a report claiming that the Feldhofer individual was simply an early 19th century Mongolian Cossack afflicted by rickets, a view originally proposed by Geheime-Rath Mayer soon after the material was announced. Once the antiquity of the Neandertals was established, researchers began to develop hypotheses regarding who the Neandertals were and what relationship they had to modern human beings.

While many proponents of Darwin's theory of descent with modification were willing or even eager to accept the Neandertal material as evidence of an intermediate in our evolution, the prevailing view quickly became that Neandertals were much too primitive in form to be directly related to modern human beings. This development could be considered an unhappy circumstance, as the more spectacular Neandertal discoveries in France overshadowed the description of the large, fragmentary Krapina sample from Croatia. Furthermore, several important French finds at this time, such as Le Moustier and La Chapelle-aux-Saints in 1908, La Ferassie in 1909, and La Quina in 1911, were published in a sequence that became quite detrimental to the interpretation of

Neandertals for years to come. The description of Le Moustier was delayed and incorrectly reconstructed, while La Ferassie was trusted to Marcellin Boule, who was preoccupied with the description of La Chapelle. When Boule published his description of La Chapelle, it overshadowed the La Quina find and quickly became the penultimate description of Neandertal morphology. Unfortunately, La Chapelle was an elderly individual suffering from a variety of ailments, and Boule interpreted the material to mean that Neandertals were bent-knee walking brutes with little intelligence, much closer to apes than modern humans. This view of Neandertals dominated in academic circles until after World War II.

Boule had created the typological characterization of Neandertals based on one of the most atypical Neandertal specimens known: an older individual afflicted by a suite of pathological conditions. While the French Neandertal material created the dominant image of Neandertals, the Krapina assemblage was also available to these early researchers, an assemblage that not only clearly indicated that the anatomy of La Chapelle was not typical of Neandertals, but one that gave a sense of the wide range of variation seen within this population. The lack of the recognition of this variation underlay much of the early work that unequivocally dismissed Neandertals from the ancestry of modern humans.

Morphology of the Neandertals

The question of what makes an individual a Neandertal is a difficult one to answer because, while many *autapomorphies* or unique derived characters have been proposed for the Neandertals over the years, none are true autapomorphies. Some proposed features are characteristic of Neandertals from only particular geographic regions, many are found in some modern human populations in varying frequencies, and others are known to be present in more archaic populations and represent primitive characteristics. Regardless of the degree of contribution to the modern human genome, the Neandertal morphotype is essentially a matter of character frequency rather than a matter of unique derived characters. While the Neandertals apparently lack true autapomorphies to distinguish them from modern humans, the suite of character traits found in Neandertals do distinguish them as a distinct group, either as a racial variant or as a closely related sister clade to modern humans.

The typological perspective common in treatments of the differences between Neandertals and modern humans is unfortunate in that it impedes an appreciation for normal variation seen in individuals within a population. As noted, there are no true autapomorphies in Neandertals that unequivocally exclude them from having had gene flow with contemporary populations in other parts of the world or from contributing to the Upper Paleolithic populations that follow them. This creates a quandary when we compose a list of morphological characteristics that distinguish Neandertals, as there are not many features that we can use to distinguish them from their ancestors, from contemporary populations, and from modern humans at the same time. Instead, we make a more useful distinction when we compare Neandertals to these other populations individually and describe how they differ from each group as opposed to the characters that distinguish them as a group.

Although we cannot overstate the importance of viewing characteristics of Neandertal morphology from the perspective of evolutionary trends rather than simple typology, a number of general morphological features characterize Neandertals inclusively. Lambdoidal flattening at the rear of the parietals and top of the occipital creates a short vertical face to the occipital, forming the characteristic “bunning” seen in Neandertal crania. This feature results in the elongation of the cranium, so that the central limit of the nuchal muscles is delineated by small pits on the occipital called suprainiac fossae, rather than the external occipital protuberance on the vertical surface, as seen in modern humans. The suprainiac fossae are generally superior to another Neandertal characteristic, the occipital torus, which is a bony ridge that runs horizontally along the occipital. Another consequence of the cranial elongation seen in Neandertals is the position of the foramen magnum more anterior relative to the position of the external auditory meati. In earlier pre-Neandertals as well as in modern humans, when a line is drawn between the external auditory meati, the foramen magnum is positioned posterior to the line, but in Neandertals the foramen magnum is positioned much more anteriorly, so that the line passes behind the foramen magnum. This positioning improves the leverage of the sternocleidomastoid muscles, which act to turn the head and stabilize the head during anterior teeth use. The improved leverage in Neandertals results in a reduction of the strength of the muscles needed to perform

these actions, and, therefore, a reduced attachment area represented by a reduced mastoid process. While the mastoid process is reduced in size in Neandertals, the juxtamastoid process just medial to the mastoid process is well developed, often larger than the mastoid process. This area marks the attachment site for the digastric muscle, which retracts the mandible, suggesting an adaptation to anterior tooth loading. These changes to the temporal region may be partially responsible for the inner ear morphology seen in Neandertals that Fred Spoor claims as a potential autapomorphy in Neandertals.

Neandertals are also characterized by a well-developed supraorbital torus. This bar of bone across the top of the eye sockets is much reduced relative to earlier pre-Neandertals and is formed by two arches that follow the contour of the orbitals with a supratotal sulcus separating them. The reduction relative to earlier forms is a consequence of absolute reduction in robusticity, as well as the frontal rising more anteriorly. In Neandertals the supraorbital torus is characterized by the expansion of the frontal sinuses. The maxillary sinuses are also expanded in Neandertals, creating a puffy midface appearance on either side of the nasal aperture, such that most Neandertals lack a canine fossa. The zygomatics are swept backwards, facing much more laterally than seen in non-Neandertal populations. Another prominent feature of Neandertals is their large nose. Neandertal noses are characterized as both very wide and very tall, with the wide nasal breadth apparently a feature inherited from their ancestors and the increased nasal height a Neandertal character. Considered together, these features combine to give Neandertals the appearance of well-developed midface prognathism.

The mandible form also shows a number of features we use to characterize Neandertal morphology. Most individuals have a retreating mandibular symphysis, thereby lacking a mental eminence or chin. The lack of a chin is widely used as a peculiar Neandertal trait, but many later Neandertals have some degree of development of this feature, and many archaic *Homo sapiens* lack a well-developed mental eminence. Many Neandertal mandibles have a retromolar space, which is a space on the horizontal ramus of the mandible between the distal surface of the third molar and the anterior border of the ascending ramus. The horizontal-oval morphology of the mandibular foramen on the internal surface of the ascending ramus is another trait characteristic of Neandertal mandibles.

This morphology is created by the strong development of the sphenomandibular ligament insertion site, thus, probably related to the strong masticatory musculature of the Neandertals.

Neandertals have relatively reduced postcanine dentition compared to their antecedents, but their size is larger than that seen in most modern human populations. The anterior dentition of Neandertals, however, is enlarged over any earlier, contemporary, or later humans. Characteristic wear patterns seen in many Neandertal individuals indicate that they probably used their anterior teeth as tools, likely for use as vices to clamp down on material that was being worked.

Neandertal brains have always been characterized as being absolutely large, with many researchers emphasizing that Neandertals had bigger brains than modern humans. This is not quite correct and is an interpretation that was influenced by several biasing effects. There are many more male than female crania among the known Neandertal specimens for which a cranial capacity may be confidently determined. With a degree of sexual dimorphism grossly similar to modern humans, this means that the mean cranial capacity is skewed toward the larger male size. For example, the middle sex mean for Würm Neandertals is approximately 1430 cc, a figure that compares favorably with many modern populations. In fact, when compared against body size, Neandertals are slightly less encephalized than modern humans. Neandertals had appreciably larger brains than their Middle Pleistocene ancestors, however.

In general, the postcranial morphology of Neandertals is little differentiated from that of modern humans. Almost all characteristics of the Neandertal skeleton fall within the modern human range, often most similar to modern cold-adapted populations such as Eskimo groups. Some of the features peculiar to Neandertals includes the morphology of the axillary border of the scapula and the shape of the pelvis. In modern humans, the axillary border of the scapula has a ventral thickening for the insertion of the teres minor muscles, while the majority of Neandertals have dorsal thickening indicating that the muscles insert on the back of the scapula along its lateral border. This feature has at times been argued as a Neandertal autapomorphy, but is actually present in early European modern humans and decreases in frequency in favor of first a bisulcate (dorsal and ventral thickening), then ventral pattern. There are also

known examples of the dorsal morphology in modern humans of particular occupations and is quite likely more a reflection of behavior than ancestry.

The shape of the Neandertal pelvis differs slightly from that of modern humans. Unfortunately, the known Neandertal specimens are male, making it difficult to make statements relating the shape of the pelvis to birthing differences between Neandertals and modern humans. In Neandertals, the superior pubic ramus is long, thin, and relatively flattened. This morphology primarily acts to widen the pelvis at the front, rotating the blades of the pelvis outward along the hip joint. This difference causes very little difference in the depth of the birth canal, front to back, and therefore likely has little to do with adaptations to birthing larger headed offspring. Yoel Rak conducted a detailed analysis of the complete Kebara pelvis and argued that the differences in the shape of the pelvis relative to the position of the femur indicate stronger abduction movements in Neandertals relative to modern humans. The significance of the morphology of the Neandertal pelvis is still subject to quite a wide range of ideas and very little agreement. Most researchers agree, however, that there was likely very little substantive differences in Neandertal gait and that such relatively minor differences may very well be the result of behavioral locomotive patterns than genetic differences.

The relative limb lengths of Neandertals reflect cold-adaptation as predicted from Bergman's and Allen's rules. Compared to body length, Neandertals tend to have relatively shorter arms and legs and distal limbs that are short in proportion relative to proximal limbs. Scientists generally accept that these characteristics are a consequence of cold-adaptation and are similar although more developed to those seen in modern human cold-adapted populations. Neandertals also tend to have much deeper and wider chests than most modern human populations, reflected by the radius of curvature of their ribs and clavicles that are long relative to their stature. These features of thicker trunk size and shorter limbs are characteristic of the cold-adapted European Neandertals and do not particularly apply to the West Asian Neandertals. This indicates that these are yet more Neandertal characteristics that result from adaptation to their environment rather than real species differences between them and modern humans.

The shape of the Neandertal trunk and limbs may explain some researchers' claims that Neandertals

were quite short, but, in reality, Neandertals show very little difference in height with modern humans. Neandertal males average 165 cm and females average 156 cm, slightly shorter (approximately one to two inches) than the European average but taller than many other modern human populations. Neandertal stature is approximately equivalent to pre-World War I French. Neandertals are not particularly short at all, simply heavily built with relatively shorter limbs reflecting cold adaptation.

Behavior of the Neandertals

Far more vigorously than differences in morphology, scientists and researchers continue to debate the cultural differences between Neandertals and early Upper Paleolithic modern humans. Evidence of behavior from the archaeological record is subject to a variety of interpretations that often reflect the bias of the researcher. Researchers who see Neandertals as significantly different from and perhaps inferior to early modern humans will invariably interpret sites and data conservatively with regard to behavioral complexity. In the same vein, researchers who view Neandertals as ancestral to later European populations consistently interpret sites and data as showing high degrees of mental and social complexity. As in all such polarized intellectual debates, there resides a middle ground.

While scientists continue to debate the degree of complexity shown by Neandertals, evidence points to a definite increase in complex behavior from the beginning to the end of the Middle Paleolithic. For example, most known Neandertal burials come from the later Middle Paleolithic, with many of them representing the classic Neandertals of France (70,000–35,000 BP). Although a few researchers question whether these burials are deliberate, the majority of researchers accept that burial was a common occurrence that became more common as Neandertals evolved over time.

We can relate behavioral complexity with other strong pieces of evidence, including

- the creation of structures at sites such as Lazaret (presumably for shelter)
- the presence of worn blocks of pigments such as red and yellow ochre or black manganese remnants in various cave sites (potentially for body adornment or for processing hides)

- pierced teeth and other beads and pendants from some later Neandertal sites (evidence for body adornment or totems)
- the flute found in Divje Babe Cave

Evidence of Neandertals' care of the sick, injured, or elderly comes from several sites where individuals show healing of cranial fractures whose seriousness likely meant the individuals were incapacitated for a period of time and, most convincingly in one male from Shanidar, who survived to maturity despite several crippling injuries that left one arm useless and also may have left him blind. While the significance of these pieces of evidence is arguable and a few researchers have vehemently challenged the validity of some of these examples, they are well-supported interpretations. As with some other anthropological sleuthing, however, the frequency of potential clues is very low, bringing up the question of whether the presence of isolated pieces of evidence for symbolic or complex behavior is enough evidence to support the contention that such behaviors were widespread, as they clearly were among later Upper Paleolithic people in Europe.

Researchers who question the strength of the evidence for such behaviors have good reason to be dubious. We know that a number of interpretations of Neandertal behavior were incorrect. For example, researchers have strongly criticized the widely reported Shanidar burial with flowers, the Teshik-Tash burial surrounded by goat horns, and the Neandertal bear cult. The presence of grave goods in many of the reported Neandertal burials is also suspect, considering that the so-called artifacts are no different than the debris found in surrounding sediments. While the presence of grave goods is unlikely, other mortuary practices may be indicated by the evidence for secondary burial and defleshing at Krapina, Kebara, and on several of the Neandertal infants.

One of the most important aspects of behavior for paleoanthropologists is subsistence behavior, in particular, meat-eating behaviors. These behaviors are important because they often leave direct evidence on fauna recovered from archaeological settings. This may be particularly important for Neandertals, as isotopic analysis of Neandertal remains indicate a very high level of animal protein, similar to that seen in high latitude indigenous Eskimo populations. The interpretation of Neandertal subsistence patterns has led to very disparate proposed behavioral and cultural

suites. Work by Mary Stiner on Italian cave sites indicated a shift in subsistence patterns from nonconfrontational scavenging prior to 55,000 BP supported by a head-dominated assemblage, to hunting behaviors after 55,000 BP supported by the presence of more complete carcasses of prime age. This work led to a flurry of speculation by researchers that earlier Neandertals were highly mobile foragers with wider geographic ranges and focused on opportunistic scavenging as well as exploitation of primarily high value foods. This argument was used to support a lack of foreplanning by Neandertals, essentially intimating roving bands of dim hominids eating whatever was available and moving on when food ran out. Only near the end of their existence did Neandertals focus on more residential behavior with less expedient tool use, wider exploitation of food resources, and active hunting of particular game. However, the assemblages on which these analyses were conducted were earlier in the century. Curtis Marean made a convincing argument that changing excavation techniques artificially created the differences between the two time periods, and he followed the argument with analyses of other Middle Paleolithic sites that have been excavated with different procedures that showed no evidence of scavenging as a major subsistence pattern in Neandertals. This interpretation is convincing, considering the presence of spears as early as 450,000 BP at Schöningen, and many sites throughout the Middle Paleolithic show a single-species-dominated faunal assemblage indicative of selective hunting. In fact, Marean has found no meaningful difference in subsistence patterns between Middle and early Upper Paleolithic sites based on faunal collections. From the perspective of hunting behavior and carcass processing, the shift in tool technology does not necessarily mean a shift in subsistence behavior.

Other direct pieces of evidence for behavior in the Neandertals are the tools that they created and used. The designation of the Paleolithic stages is based upon technological types, and, therefore, the transition from the Lower to the Middle and the Middle to the Upper Paleolithic took place at different times in different places. The pre-Neandertals used the Acheulean industry that is associated with bifaces, stones flaked on both sides to create the cutting edge. The typical Acheulean form is that of the teardrop-shaped hand axe. As the Neandertals emerged approximately 250,000–200,000 years ago, there was a shift from the typical Acheulean industries

to the Middle Paleolithic Mousterian industries. Mousterian industries are the principal technology associated with Neandertals. This industry appeared in various forms, including a Mousterian of Acheulean tradition that includes a large component of hand axes, as well as more complex forms with a high frequency of burins, side scrapers, points, and denticulates. Many of the Mousterian assemblages are associated with the Levallois technique of flake removal around a core, followed by blade removal from the center of the core across the dome created by peripheral flake removal. The Upper Paleolithic is associated with high frequencies of blades (flakes more than twice as long as wide) and common use of bone and antler rather than stone. The Middle to Upper Paleolithic transition was more of a transition in frequency of tool usage rather than the invention of new tool types, as Upper Paleolithic type tools have been found at varying frequencies from the Lower Paleolithic upward. While the differences may be more quantitative rather than the qualitative that is often described, there are particular identifiable features in Upper Paleolithic industries. There are two Upper Paleolithic traditions of primary importance in the discussion of Neandertals: the Châtelperronian and the Aurignacian. The Châtelperronian is definitively a Neandertal technology, while the origins of the Aurignacian are less clear. The Châtelperronian is characterized by backed bladelets, and while the Aurignacian was similar in many ways to the Châtelperronian, it was characterized by much more use of bone and antler in tool production, the creation of split backed bladelets, and barbed spear points with more developed hafting.

Many researchers have argued for a cultural revolution in the shift from the Middle to Upper Paleolithic, but the actual shift was more of a gradual change that occurred at various times across the European landscape. It may very well indicate more complex behavior, but, although the tools are seemingly more sophisticated, they are actually no more difficult to manufacture than Mousterian tools and do not seem to perform functions distinctly different than that of earlier assemblages. There are differences, and some hypotheses have been proposed to explain differential behavior, such as Olga Soffer's proposition that the need for more microblades was to thinly fillet meat for drying, allowing food storage. These behaviors do definitively occur later in the Upper Paleolithic, but during the important period of transition and the

disappearance of the Neandertals, there is little unequivocal evidence for these behaviors. The bulk of the information available on Neandertal culture does not lead to an unequivocal conclusion regarding Neandertal behavior and affinity, or lack thereof, with early modern humans.

Replacement of Continuity?

Two polarized positions—the *replacement model* and the *continuity model*—characterize the argument over the fate of the Neandertals. The extreme manifestations of these positions is that Neandertals were either summarily replaced by invading anatomically modern humans or that they evolved in situ into modern Europeans. As we have gained a better understanding of population genetics and speciation over the past several decades, scientists have abandoned completely the extreme continuity position, but with the development of mitochondrial DNA (mtDNA) studies of both modern human groups and several short Neandertal and early Upper Paleolithic modern human mtDNA sequences, more scientists have embraced the extreme replacement model. Although the extreme positions may be easiest to characterize, a wide range of hypotheses exist regarding the degree of potential interbreeding between Neandertals and populations of early moderns outside of Europe.

The argument involves three primary pieces of data: skeletal morphology, technological industries, and population genetics. Replacement models have their history in the erroneous description of La Chapelle by Boule and the initial discoveries of early modern humans that were thought to be direct ancestors of modern Europeans (for example, Galley Hill and Grimaldi). The contemporaneity of the Neandertals and early moderns led to the development of the Presapiens Hypothesis proposed by Boule and Sir Arthur Keith and later developed by Henri Vallois. The hypothesis posited that the lineage leading to Neandertals and the lineage leading to modern humans split early in the Pliocene (between 5–2 mya) and diverged along separate evolutionary trajectories. As newer finds were excavated and some older finds were shown to be misdated or fraudulent (such as Piltdown), the Presapiens Hypothesis gave way to the PreNeandertal Hypothesis, which suggested a more recent split just before the last glacial. The fundamental point of both theories was that early moderns and Neandertals coexisted in Europe at the same time.

Thus, the Neandertals could not be ancestral to early modern humans.

During this time, following in the intellectual footsteps of researchers such as Carleton Coon and Ales Hrdlička that pointed out affinities between Neandertals and later Europeans, Franz Weidenreich proposed a multiregional theory of human evolution. Weidenreich suggested that a single ancient form ancestral to all modern humans (and Neandertals) had spread across the Old World and had adapted to its own environments while sharing enough gene flow to maintain a single species, developing differences that are seen in geographic races today. In this candelabra view of human evolution, Neandertals are simply an ancient race of modern human beings that are directly ancestral to the population sharing the same geography as them, modern Europeans. In response, William Howell proposed the “Noah’s Ark” model in which all modern humans developed from a more recently evolved form in Africa that then spread around the Old World, replacing indigenous ancient humans (such as the Neandertals).

In the 1960s and 1970s, the debate took on much of its modern form. Loring Brace pointed out that many of the apparent morphological differences between Neandertals and modern humans were not as extreme as some had claimed and that many of the features could be related to relaxation of evolutionary pressures to maintain robust structures via the development of more advanced technology. In Brace’s arguments, Neandertals developed Upper Paleolithic technology and cooking technology that led to gracilization of cranial form that put them on a trajectory toward modern Europeans, not necessarily requiring any gene flow from “more advanced” forms from Africa and West Asia. Following Brace, Milford Wolpoff restated Weidenreich’s multiregional model, focusing on regional characteristics seen in modern human populations and arguing that these differences appeared first in the regional *Homo erectus* populations and gene flow between regions maintained species integrity, ensuring that evolutionary trends were shared between all human populations. Shortly afterward, a group of researchers such as Christopher Stringer and Günter Brauer became convinced that the differences between modern humans and Neandertals were too great to be the result of “short” term evolution during the Middle to Upper Paleolithic transition. These researchers published a number of works highlighting the differences between Neandertals and

early moderns that showed that the modern human cranial form appeared first in Africa and spread into Europe, replacing the Neandertals. The Out of Africa and Multiregional model battle lines were firmly drawn at this stage. The proponents of replacement focused on the differences between Neandertals and moderns and argued that these differences were too great for the time period that it would take for the evolution from one to the other; they believed that the earliest modern forms occurred in Africa. The proponents of continuity focused on the similarities between the Neandertals and later modern humans and argued that there was a clear evolutionary trend leading from one to the other.

If we are to objectively analyze the relationship of Neandertals to the early moderns that succeeded them, we must review several pieces of paleontological and archaeological evidence.

1. With regards to technology, Neandertals are known to have created the Châtelperronian industry, meaning that they were capable of developing the technology characteristic of the Upper Paleolithic.

2. The earliest known modern humans associated with the Aurignacian postdate Neandertals in the geographic regions in which they are found. A number of intermediate sites in the 40,000–30,000 BP range exist where lithic materials are either unas- sociated with any human remains or are associated with undiagnostic fragmentary material such as isolated teeth. Some researchers have claimed these show Neandertal affinities and, alternatively, some have claimed they show modern human affinities. However, these remains are not diagnostic to group affiliation, making their use in either argument unconvincing.

3. Site usage patterns are often extremely similar in Middle and early Upper Paleolithic sites, as are subsistence patterns.

4. Early Upper Paleolithic modern humans show a variety of morphological characteristics that are unknown or rare among the few earlier African modern forms or in the early anatomically modern human forms from Qafzeh and Skhūl in West Asia but are widespread in Neandertals. These same features decrease in frequency through the Upper Paleolithic, Mesolithic, and Neolithic until they are rare or nonexistent in Europeans today.

5. The rate of evolutionary change needed to go from the Neandertal form to the early Upper Paleolithic modern human form is less than is known in the same features among later European moderns. Essentially, the time needed to evolve the modern form from the Neandertal form is a non sequitur, because it is based not on the differences between Neandertals and their immediate successors, but rather on either non-European contemporaries or modern Europeans.

6. A factor rarely considered is the glaciation cycle in Europe and the effect it had on depopulation in Europe. The Neandertals “disappeared” from much of Central and Eastern Europe during a time of extreme glaciation, and a similar gross reduction in human populations in Europe occurred during the last glacial maximum in the Mesolithic. These facts are difficult for the replacement without interbreeding models to deal with, as they seem to point toward Neandertals evolving toward the modern condition, perhaps with strong influx of non-European moderns during the last few interstadials when the ice sheets receded, exposing Europe to colonization with a much reduced indigenous Neandertal population. While comprehensive analysis of the archaeology and anatomy does seem to support the continuity argument, the development of the mtDNA data revolutionized the debate and shifted the consensus opinion squarely to the replacement camp, and created data that are particularly difficult for multiregionalists to satisfactorily explain.

In 1987, the journal *Nature* published a paper by three molecular biologists who argued that the known restricted variation in modern human mtDNA could be interpreted to mean that the ancestors of modern humans went through a genetic bottleneck in Africa between 280,000 and 140,000 years ago, and then spread throughout the rest of the world without intermixing with indigenous populations. The analysis was attacked on a number of grounds, but further analysis of mtDNA variation and distribution supported the initial claims, with only slight modification of the dates involved. The replacement proponents took this data as unequivocal support for the Out of Africa model of human evolution. In 1997, a small sequence of mtDNA was recovered and amplified from the original Feldhofer Neandertal individual by Svante Pääbo and colleagues. The variation in the sequence was at the very edge of known modern

human variation and statistically supported a split between the lineage leading to Neandertals and the lineage leading to modern humans between about 690,000 and 550,000 BP. Samples from several other Neandertal specimens and a few early modern humans were recovered that seem to strongly support the contention of an early split between the two lineages.

For many, this definitively answers the question of Neandertal ancestry for modern humans, with the new question how and why they became extinct. Scientists and researchers have put forth a number of arguments, including violent replacement of Neandertals by invading moderns, deteriorating conditions resulting in the decline of the Neandertals and the expansion of moderns into their previous geographic range, and indirect competition between the more behaviorally “primitive” Neandertals and the more “advanced” moderns leading to a decline and extinction of the Neandertal clade. Some researchers propose that absolutely no interbreeding occurred between populations, while others accept statistically insignificant interbreeding as a possibility, and others propose a “genetic swamping” of Neandertal genes by the much greater numbers of moderns leading to the eventual extinction of Neandertal mtDNA lineages rather than a complete lack of Neandertal ancestry for modern humans. This last position is functional similar to many multiregional models but differs on the issue of evolutionary trends toward modernity within the Neandertals and the degree of gene flow during earlier eras that link the two populations as species.

The debate is not so easily resolved, however, and many multiregionalists point to the fact that much of modern human nuclear DNA does not show the same pattern of extreme bottlenecks traceable to approximately 200,000 years ago. A number of analyses have given nuclear DNA coalescence dates much closer to one million years or more. Molecular geneticists have, however, attacked these analyses, and it is unclear whether they support multiregional claims. A greater problem with the molecular data is the nature of the data themselves. Studies on mtDNA bottlenecks are analyses of variation within particular sequences that have relatively well-known mutation rates. A coalescence date is determined by working backward from the variation seen in a population, presuming a constant mutation rate, to a single sequence with no variation. From the number of mutations needed and a generation time, we may calculate a time range. This method necessarily is unable to deal with the biological

reality of expanding and retracting variation of varying strengths throughout evolution or stasis created from relatively stable population levels. The analytical method works best for evaluating the situation it is modeled after: a period of much reduced variation followed by a relatively stable period of expansion in variation to the modern level of variation. While the molecular procedures and analytical methods are becoming more advanced and providing greater confidence in the results themselves, the continuing question of many multiregionalists is what the significance of the results actually are in the context of complex population genetics.

Neandertals were the first nonhuman hominids discovered and have been the focus of some of the most strident debate in paleoanthropology. A seemingly endless number of morphological features, cultural characteristics, and, in modern times, genetic analyses have been used to either differentiate them from modern humans or include them as an ancient variant that contributed to modern humans. Often the questions asked about them are less a reflection of objective scientific inquiry about an extinct human population than a reflection of the most basic question in anthropology: What makes us human?

NEANDERTALS

Anthropologists still disagree as to whether modern humans descended from Neandertals. There are three schools of thought: those who think we are descendants of the Neandertals, those who believe the Neandertals are a completely different species, and those who are reserving final judgment until more evidence is discovered.

Those who see the Neandertals as a separate species cite the fact that Neandertal behavior was very different from the behavior of other hunter-gatherers. Proponents of this theory believe that the thought processes of the Neandertals were significantly different from those of modern humans in that they did not seem to anticipate future needs. The skull shape and brain shape of the Neandertal are quite different from those of present-day humans. Some believe that this was a matter of survival of the fittest, and that the Neandertal could not compete after the better-adapted *Homo sapiens* arrived on the scene. The Neandertals, with their huge protruding nose, large brow ridges, and laterally facing hip sockets, differ

greatly from *Homo sapiens*. They would have walked with a distinctive gait unlike ours. It is also likely that the Neandertals had little ability to use spoken language because of the structure of their upper respiratory tracts. These scholars believe that Neandertals were loners, not living in family groups. Neandertal males devoured meat wherever they killed it, rather than taking it home to a family, and most females seem to have survived on a diet of plants and small animals.

Other respected anthropologists believe there is no question that modern humans evolved from Neandertals. These scientists refute the theory that Neandertals could not speak, based on a discovery made in Kebara Cave in Israel in 1982. A hypoid bone from the throat and larynx of a 60,000-year-old Neandertal was found there, and it was determined to be indistinguishable from that of a modern human. To many scientists, this proved that the Neandertals could speak. Some of the same proponents of our Neandertal ancestry cite evidence that Neandertals lived in groups and were provided for and protected by the group. Neandertals survived for more than 100,000 years. They buried their dead, dug flint from quarries so fashion spear tips, and had crude musical instruments.

The debate will likely continue as we unearth more evidence that supports one school of thought over another.

NEO-DARWINISM, ORIGIN OF

What is the theoretical framework of modern biology? If we would question a professional biologist, or even an eager reader of popular books on biology, we would await the answer: Darwinism, that is, Charles Darwin's theory of evolution by natural selection. But this answer is not entirely precise. Of course, Darwin's position in the history of biology can be compared to that of Galileo Galilei in the history of physics. But it would be surprising if the nearly 150 years since the first publication of Darwin's main work, *On the Origin of Species* (1859), had not brought forth new discoveries and fresh theoretical ideas that changed

the original version of Darwinism. And, indeed, this was the case. Therefore, a terminologically more precise answer to our initial question would be that Neo-Darwinism is the theoretical framework of modern biology.

What are the most important theoretical developments after Darwin that shaped Neo-Darwinism? The title *Neo-Darwinism* was used in the history of evolutionary thought to denominate, above all, the following three theoretical developments:

- August Weismann's panselectionism assumed that natural selection works, not only on the level of organisms, but also on the levels of chromosomes, cells, and populations (since the 1870s).
- Theoretical population biology constructed mathematical models for the workings of natural selection in the history of life (since the 1910s).
- The Modern Synthesis integrated all subdisciplines of biology into an overall picture of Darwinian evolution (since the 1930s).

Contemporaries called the evolutionary thought of the German biologist August Weismann (1834–1914) Neo-Darwinism (or even Ultra-Darwinism) because he extended the range of the Darwinian principle of natural selection so that it comprised the struggle for existence, not only between organisms, but also between populations, cells, and chromosomes. Weismann did much experimental research on specific biological phenomena in the light of evolutionary theory, and he interpreted his experimental results with the help of courageous conceptualizations. That is why Weismann can be called the second most important Darwinian of the 19th century (excelled only by Darwin himself).

We shall give a first impression of the importance of Weismann's work by describing how he embedded the empirical falsification of a then widely accepted genetic theory into a new conceptual framework, and how he used this framework to sketch a radical Darwinian picture of the evolution of life.

Weismann tested experimentally, in the years 1875 to 1880, the theory of the inheritance of acquired characters. The idea that organisms transmit knowledge acquired by practice and learning genetically to their offspring was developed into a biological theory by the French biologist Jean Baptiste de Lamarck at the beginning of the 19th century. From edition to edition of *On the Origin of Species*, Darwin more and

more became a Lamarckian in genetics. Weismann tested Lamarckism by experimenting with lines of mice, whose tails he cut generation after generation. But he did not succeed this way in breeding mice that have shorter tails as compared to mice of the same origin whose tails were never cut.

How to explain this result? Weismann developed, in the first half of the 1880s, the theory of germ-plasm. He distinguished two types of cells in every organism: germ cells and somatic cells. The germ cells (in sexually reproducing organisms, the male sperm and the female egg) secure the reproduction of an organism by means of the germ-plasm they contain in their nuclei. It is, in modern terms, nothing else than the carrier of genetic information. All other functions of the organism are fulfilled by somatic cells.

Then Weismann postulated that the differentiation of somatic cells during the development of an organism is controlled by the structure of the germ-plasm. Additionally, he proposed that somatic cells do not have any retro-effects on the germ-plasm, so that Lamarckian inheritance of acquired characters is not possible. The continuity of the germ line from generation to generation is thus declared to be the fundamental base of evolution. Phenotypical variation of somatic cells is caused by genotypic variation.

What does, in turn, cause genotypic variation? Because Weismann considered the components of the germ-plasm (which he could identify with the chromosomes) as being little self-replicating and metabolizing systems, he came to the conclusion that the struggle for existence, and thus natural selection on the molecular level of the germ-plasm ("germinal selection"), is the ultimate cause of genotypic variation.

In his famous lectures on evolutionary theory, which filled three voluminous editions that were published between 1902 and 1913, Weismann integrated his genetic determinism into a radical Darwinian picture of evolution. He extended the explanative scope of the principle of natural selection from the level of organisms, the level on which Darwin had studied it, to other levels of the hierarchy of biological organization. Weismann's pan-selectionism assumes that natural selection works also on the level of populations, organisms, cells, and germ-plasms.

By so doing, Weismann could not only analyze separately the constraints on selection for every level and describe the role of each level in the development of an organism and in the history of life, but also have a synthetic look on the interactions of all those levels

in an ecological environment. So, events concerning whole populations can strongly influence the dynamics of selection on lower levels, such as if a natural catastrophe were to isolate a population. Therefore, every level constitutes a boundary condition on the mechanism of natural selection on all other levels.

Weismann represented selection-driven evolution as the natural dynamics of a self-regulating hierarchical system of biological organization. This system has a center of gravity: germinal selection between chromosomes. Weismann's emphasis on genetics lets us understand why the most radical of today's Neo-Darwinians, like Richard Dawkins, still accept the name "Weismannism" as an adequate denomination of their evolutionary thought.

Whereas the overall architecture of Weismann's evolutionary thought of evolution has an up-to-date outlook, important parts of his theory of inheritance were falsified by empirical research on molecular genetics. The functional distinction between germ cells and somatic cells had to be reshaped into a difference between nucleic acids and proteins, which are components of every cell. Weismann's idea of germinal selection as resulting from a direct struggle for survival between chromosomes is, taken literally, completely false.

But the main obstacle to Weismann's project of constructing a pan-selectionistic picture of evolution centered in genetics was not his lack of biochemical knowledge. He simply knew too little about formal genetics. Weismann learned about Gregor Johann Mendel's genetics of discrete hereditary units, first published in 1866, just when it was rediscovered in 1900, although he had prepared the ground for this rediscovery by postulating the existence of such units in the germ-plasm.

Weismann lived too early to get the chance to base the Darwinian theory of evolution on Mendelian genetics. The feat of doing this and of developing a new kind of Neo-Darwinism was performed by the three founding fathers of theoretical population genetics, Ronald Aylmer Fisher (1890–1962), John Burdon Sanderson Haldane (1892–1964), and Sewall Wright (1889–1988), who published their foundational works between World Wars I and II.

Theoretical population genetics is the biological discipline that tries to construct a formal theory of evolution, which must be inspired and controlled by empirical research. A theoretical population geneticist understands natural selection as a hypothesis that

can be established by mathematical models of the origin of evolutionary mechanisms.

Fisher, Haldane, and Wright began to describe the most various biologic phenomena by their quantitative effects on the frequency of genes in populations with Mendelian inheritance. Thereby, they founded theoretical population genetics as the core discipline of this second type of Neo-Darwinism. Because a complete survey even of the works of those founding fathers is not possible here, I shall concentrate on Fisher's theory, who is well known for his work not only in mathematical genetics, but also in statistics and experimental design.

Fisher's fundamental insight in evolutionary theory was that natural selection is not a principle that must be axiomatically posited instead of being deduced from natural laws. If biologists knew the laws of variation and heredity, could embed them in a model of ecological dynamics, and had sufficient data about present-day biodiversity at their disposal, they should be able to deduce natural selection as the resultant mechanism by which life on Earth has evolved.

The first sentence of Fisher's main work in genetics, *The Genetical Theory of Natural Selection* (1930)—"Natural selection is not evolution"—contains implicitly his fundamental insight. Fisher saw that

natural selection is an abstractly describable mechanism that can be described formally without referring to the history of life on Earth. But its mathematical description also states which conditions real evolution must meet if natural selection is to be accepted as an explanatory rule in biology.

On the basis of his fundamental insight, Fisher formulated a theorem that he called “the fundamental theorem of natural selection.” Why fundamental? Fisher drew an analogy between his theorem and the second law of thermodynamics, which describes statistically how a measurable property of an aggregate of units, the specific nature of which is not important for the formulation of the law, increases constantly. And the same is true for Fisher’s fundamental theorem. It describes the adaptive improvement of organisms that is caused by natural selection in a population, which is supposed to live in a constant environment and within which do not happen any arbitrary fluctuations in the gene pool.

Fisher’s theorem states that “the rate of increase in fitness of any organism at any time is equal to its genetic variance in fitness at that time.” What does this mean in more informal terms?

We have to remember that the fitness of an organism is defined as the number of its adult offspring. If an organism is better adapted to its environment than its rivals, its chances are better to also have a higher fitness. Transposed to the genetic level of a population, this means that the fitter an organism, the higher the relative frequency of its genes in the genetic pool of its population.

Now, natural selection causes the average fitness of our idealized population to always increase over time. But how fast? Fisher’s fundamental theorem gives the answer. The more the organisms in the population vary in fitness, the faster this increase will turn out. This is intuitively evident. If there is, for example, a difference in fitness between two subpopulations, the subpopulation with higher fitness will have more offspring than the one with lower fitness proportional to their difference in fitness. Eventually, the offspring of the fitter subpopulation will make up the whole population. The average fitness of this new population will then be, at least, the average fitness of the former subpopulation with higher fitness.

Yet Fisher was not a naïve selectionist. From his point of view, the ecological environments in which natural selection is working permanently influence considerably the evolutionary process. There are, for example, environmentally caused mutations that will probably have negative effects on the fitness of organisms. In general, all ecological changes and the simultaneous evolution of competitors in the struggle for existence set up new conditions on the adaptedness of an organism and change the average fitness of its population. Fisher called this ecological component of the total change in fitness of a population over time the “deterioration of the environment,” because it represents destructive environmental effects on well-adapted organisms.

After Fisher’s generation came to an understanding of the hypothesis of Darwinian selection as a deductive consequence of a formally describable natural dynamics, the history of theoretical population genetics has led to mathematically more and more complex models of natural history. Thereby, this second type of Neo-Darwinism formalized the Weismannian picture of evolution, which is to be explained by the dynamics

of the hierarchy of biologic organization with a center of gravity on genetics.

But the theoretical population geneticists also found astonishingly simple formulations of fundamental evolutionary laws. For example, Fisher's separation of two types of evolutionary factors, natural selection and environmental effects, can be mathematically expressed in a plain formalism using the statistical concepts of covariance and expectation value. Such an example shows that theoretical population genetics still is a very important part of evolutionary thought because it uses a high level of abstract reasoning, comparable to the use of mathematics in physics, to convey a vivid understanding of the fundamental processes of the history of life. So, it is not surprising that the most important Neo-Darwinians after World War II tried to base their theories on models from theoretical population genetics.

The formal kind of Neo-Darwinism founded by Fisher, Haldane, and Wright sometimes seems to be more similar to a mathematical than to a biological discipline. One has to learn a lot of calculus and be able to program computers in order to test the mathematical models by simulations. These models show how natural selection causes the gradual evolution of populations by calculating the change in gene frequencies. But how can they be related to the empirical reality of living populations, which the naturalist observes? What do they tell us about the origin of today's biodiversity, in which the field biologist is interested? Isn't theoretical population biology just a too-impooverished picture of nature—even on the genetic level? Does it think too mechanistically by assuming that everything is built on the base of single genes, the effects of which have to be simply added in order to generate a complex organism?

One of the men who asked all these questions very intensely since the 1930s was an ornithologist with extensive experience in field research, a staunch Darwinian with a broad knowledge of the history of biological thought, and a theoretical biologist with a deep interest in the foundations of evolutionary thinking. His name is Ernst Mayr (born 1904 in Germany), and he is one of the builders of the "Modern Synthesis," which was seen as being a renewal of Darwinian thought—a modern kind of Neo-Darwinism.

The English biologist Sir Julian Sorell Huxley (1887–1975), the grandson of Darwin's "bulldog," Thomas H. Huxley, and the brother of the famous

writer Aldous Huxley, published in 1942 his book *Evolution: The Modern Synthesis* and established thereby the "official" title for this kind of Neo-Darwinism. But why "Synthesis"?

The aim of Mayr and his colleagues was to counteract the specialization of biological disciplines by showing how the fundamental ideas of Darwinism were able to bring them all back in fertile connection. For example, the gap between abstract models of theoretical population genetics and naturalist knowledge should be bridged. This could be done only if, on one hand, the naturalists would learn the theoretical geneticists' models of gradual evolution, and only if, on the other hand, the theoreticians would take into account the naturalists' knowledge about how populations in the wild behave.

The unification of theoretical modeling and empirical research began in the 1930s. The Russian experimental geneticist Theodosius Dobzhansky (1900–1975), who worked since 1927 in Thomas Hunt Morgan's famous *Drosophila* research group first at Columbia University and then at the California Institute of Technology, connected his empirical research to Darwin's evolutionary theory in his book *Genetics and the Origin of Species* (1937). This publication has to be honored as the starting signal of the Modern Synthesis. The programmatic allusion of the title of Dobzhansky's book to the main work of Darwin is clear. The same is true for the following important document of the Modern Synthesis.

Ernst Mayr, who worked since 1932 at the American Museum of Natural History in New York, wrote an important book on questions of taxonomy and gave it, in parallel to Dobzhansky's, the title *Systematics and the Origin of Species* (1942). In it, he tried to answer the question of speciation: What are the processes responsible for the origin of new species? This question was not systematically treated by Dobzhansky.

It is, by the way, an interesting question whether it was necessary that two biologists of continental European origin and traditional taxonomic training were implanted into the Anglo-American environment of genetic thought in order to start the unification project of the Modern Synthesis.

That the Modern Synthesis was swiftly successful in the research community of evolutionary biology became evident at a 1947 conference in Princeton, New Jersey, where some of the most important biologists gathered. The proceedings of this conference

were published under the title *Genetics, Paleontology, and Evolution* (1949), and they document that the Modern Synthesis ruled over the evolutionary Zeitgeist. This title brings together three main aspects of the history of life seen from the Neo-Darwinian perspective: first, the base for the transmission of biological information from one generation to the next, whereby evolution is made possible; second, the fossil data to reconstruct the concrete course of evolution on Earth; and third, the resulting process of evolution itself.

Today, Mayr considers the Modern Synthesis to have been confirmed in the past 60 years by innumerable empirical findings, especially in the field of molecular genetics (like the discovery of deoxyribonucleic acid as the carrier of genetic information). Yet the history of Darwinism did not stop after the Modern Synthesis found a codification at the end of the 1940s.

An important tendency was that the evolutionary biologists came, compared with the Modern Synthesis, to an even more radical understanding of the foundation of the history of life on genetic processes, so that we can even diagnose a return to Weismann. This "Neo-Weismannism" uses formal models of evolutionary processes (via theoretical population genetics), and its genetic theory is based on the knowledge of the biochemistry of inheritance (via molecular genetics).

Three kinds of Neo-Darwinism arose successively in the history of biology and are still important for current debates on evolutionary theory. They show many important differences but have also some main features in common, such as their emphasis on natural selection and their theoretical base in genetics.

The bold outlook of today's Darwinism should not suggest that the foundational problems of biology are all solved. Nowadays, it is clear that mechanisms other than selection are effective in evolution. One important example is, on the molecular level, genetic drift, that is, the spread of selectively neutral genetic information in the gene pool of populations. How these mechanisms played, and still play, together in the history of life is a heavily debated topic.

Perhaps Darwin's theory of natural selection need not be supplemented only by other evolutionary mechanisms. Perhaps it must be integrated together

with them into a new conceptual framework. Then, Darwin would remain biology's Galilei, but some day he would be succeeded by its Newton.

NEO-DARWINISM

Neo-Darwinism is the "new" Darwinism. It is a blend of Charles Darwin's 19th-century theory of evolution through natural selection and Austrian biologist Gregor Mendel's theory of genetic inheritance. It states that evolution takes place because of slow changes in the environment. Those individuals within a population that have characteristics adapted to the new environment are the ones most likely to survive and reproduce, passing on those characteristics. Eventually, this can lead to the formation of a new species.

Darwinism is based on Darwin's treatise, *On the Origin of Species*, which he wrote in 1859. Scientists immediately hailed it as a viable alternative to creationism, which some thought was mere conjecture. Darwinism is based on several observations about living things. These include the

observations that offspring generally outnumber parents, species numbers generally remain fairly constant, and that individuals differ in small ways and inherit these differences from their parents. The conclusion he drew was that individuals whose variations best allow them to adapt to their environment will be more likely to survive and reproduce. This is commonly called the principle of natural selection. Darwin incorrectly believed that characteristics of the parents were transmitted to the young through the blood.

Darwinists believe that Darwin's theory explains the origin of all biological species. On the other hand, creationists and other non-Darwinists argue that evidence to prove this is totally lacking. Neo-Darwinism blends Darwinism with genetics. In 1866, Mendel published a paper showing that characteristics were transmitted by what we now call genes. Geneticists found in the 1930s that a variety of genetic errors can occur during reproduction. These are known as mutations. In order for Neo-Darwinism to be true, some mutations must be beneficial to the organism. Most of the mutations that have occurred in humans have proved to be harmful. Therefore, Neo-Darwinism asserts that evolution will be a long, slow process.

Neo-Darwinism is also known as the modern synthesis because it synthesizes, or brings together, Darwinism and modern genetic theory. The theory is still not universally accepted by scientists, however. Some questions remain unanswered. For example, why have some organisms evolved greatly while others have scarcely changed over millions of years? Nearly 150 years after Darwin advanced his theory, the controversy still rages between the creationists and those who believe in Neo-Darwinism.

NEOLITHIC CULTURES

The term *Neolithic* is frequently used to refer to that stage in humanity's history when people became sedentary and started farming. The Neolithic is normally conceptualized as a package that includes farming, sedentism, the making and use of stone tools, and

crafts such as pottery and weaving. It is thus viewed as a new food-producing economy that, following Andrew Sherratt, eventually led to the Secondary Products Revolution, when people intensified production and labor and made use of secondary products, such as milk, traction, and wool. The Neolithic is also viewed in terms of what Service termed tribes and chiefdoms.

Although this general view sometimes captures the spirit of the Neolithic, it presents a homogenized picture of a time frame that is as varied geographically as it is materially. The concepts of Neolithic and Secondary Products revolutions imply a definite break with the preceding period, the Mesolithic, and a universal, homogeneous change in lifestyle. Moreover, the long-standing emphasis on tribes and chiefdoms has led to Neolithic tribes being defined by what they lack, rather than by what they have.

The idea of economic revolution was mostly articulated by Vere Gordon-Childe, who was influenced by both culture-history and Marxism. Childe saw the Near East as the starting point for the Neolithic, with the Natufians branded as the first farmers. In his view, plant domestication preceded animal domestication.

It was Robert and Linda Braidwood who, in 1948, launched the Iraq-Jarmo project to recover primary evidence for the earliest food-producing economies in the Near East, long considered the cradle of civilization. The work at Jarmo, coupled with Willard Libby's new C14 lab at the University of Chicago, indicated that, contra Childe, the earliest food-producing economies had been in the hilly flanks of the Fertile Crescent rather than lowland oases and riverine areas.

However, Lewis Binford and Kent Flannery came up with the marginality hypothesis, arguing that food production deliberately started around optimal-zone margins. On the other hand, Ofer Bar-Yosef and his colleagues put forward the Levantine primacy view, arguing that drier conditions between 13,000 and 12,800 BP forced hunter-gatherers westward. The consequent population increase resulted in reduced mobility; a broad-based economy; and the establishment of large, aggregated sites. What distinguishes this work is that Bar-Yosef and his colleagues consider complex social organization together with environmental change and population growth as reasons for the start of sedentism.

The New Archaeology also saw the Neolithic in terms of chiefdoms and ritual sodality, and there was

substantial focus on the origins of inequality within the Neolithic. The postprocessual movement, by contrast, focused on people (rather than the system behind them) and applied poststructuralism to the study of meaning and symbolism. The Neolithic thus came to be viewed as a world full of rich, symbolic meanings that are manipulated and renegotiated by social actors.

What makes the Neolithic difficult to conceptualize as a whole is the diversity within cultures. The transition from Mesolithic to Neolithic is by no means clear-cut. Moreover, the Neolithic did not spread and appear everywhere at once. In many areas (Britain being a case in point), the Mesolithic lifestyle survived far longer than conventionally thought, and for a while, it existed side by side with farming. Ethnographically, it is known that foragers are often very resistant to farming, and this seems to be the case archaeologically as well.

How the Neolithic spread remains a contentious subject, and it is unlikely that the phenomenon can be explained by a universal theory. It is also unlikely that one can explain Neolithic cultures as a monolithic phenomenon. The remainder of the discussion will focus on the Neolithic of Europe, while acknowledging that Africa, Asia, the Americas, and other parts of the world have complex Neolithic biographies.

Broadly speaking, the European Neolithic started about 7000 BC in southeastern Europe, about 6000 BC in the Mediterranean, and about 5500 BC in central Europe. The Neolithic of northwestern Europe dates only to about 4500–4000 BC. In each area, the Neolithic assumed its own distinctive character.

Southeastern Europe and Greece

The Karanovo settlement in central-southern Bulgaria dates to about 6000 BC and is built on an earlier settlement. Rectangular houses built of mud or daub had clay ovens inside. Clay figurines were also found in a domestic setting.

Such mounds, which are found in Greece, the Balkans, and as far north as Hungary, have been the subject of intense debate. Sites like Karanovo in Bulgaria and Sesklo in Thessaly were used periodically over a long time, whereas other sites (for example, in Britain; see below) were used for only short periods of time. Simply considering them in terms of a new subsistence economy would be excluding them from a wider landscape that was profoundly and constantly

manipulated and renegotiated. The new trends in economy are part of a wider change in identity in an increasingly complex world.

The Neolithic is also a time of socially important exchange networks; obsidian was traded throughout much of the Mediterranean, while in Britain, stone axes from the Langdales were found as far as Scotland and throughout much of Britain. In terms of food, wild animals were still hunted and formed an important part of the sociocultural context. Most sites, however, show a preponderance of sheep, goats, cattle, and pigs. On the plant front, cereals and legumes dominate most assemblages. Materially, pottery was present almost everywhere, and clay figurines played an important role in many communities.

This general picture of a diverse material culture applies broadly to an area stretching from Turkey to Iran, where domestication and sedentism culminated in a process lasting from 9000 to 7000 BC. By 7000 BC, there were established Neolithic communities in Hacilar and Catal Hoyuk. As Neolithic communities expanded, they settled in Cyprus, Crete, and other coastal areas. However, whereas there seem to be many people in areas like Thessaly, population density seems to be lower in the Struma, Vardar, and Danube valleys.

By 5000 BC, there appear a handful of sites with a large, centrally placed building, normally called a megaron, such as those at Sesklo and Agio Sofia. It appears that these were meeting houses. New settlements were also founded, for example, at Dimini, a site with concentric retaining walls with communal spaces and individual buildings having their own hearths.

Figurines become increasingly distinctive, with the Vinca culture producing figurines that are now almost iconic. Figurines had triangular faces, large eyes, and body decoration, and they occurred mostly in domestic contexts. Together with many other figurines from Europe and the Mediterranean, they have often been placed within a Mother-Goddess and/or fertility paradigm, one that has been challenged and debated for at least the past 50 years.

By about 4000 BC, profound changes are detected throughout the area. Most sites are abandoned, many for good. Those that are reoccupied are in a much reduced form. Although cemetery burials still continued in parts of Romania and southern Ukraine, other regions, such as those around the lower Danube and the steppe zone of southern Ukraine, opted for small

mounds. The picture in Greece also becomes more complex. Although change occurred over a wide geographic area, it was regionally different.

Central and Western Europe

The Linear Pottery culture (termed *Linearbandkeramik*, or LBK) is the first Neolithic culture in central and western Europe. It is found from western Hungary to the southern Netherlands, eastern Belgium, central-northern France, Slovakia, the former Czech Republic, Austria, parts of Poland, and Germany. LBK settlements are typically found on fertile soils and near water sources. Compared to the rest of Europe, the LBK looks far more uniform in terms of settlement location, longhouses, enclosures, and cemeteries. There are similarities in stone tools and pottery, but toward the end of the phase, pottery styles became more regionalized.

Although the LBK has been presented as a clear-cut case of a break with the preceding Mesolithic, scholars like Alasdair Whittle point to evidence for continuity, noting that physical and anthropological evidence from cemeteries is compatible with continuity of indigenous populations. Moreover, he notes that the basic flint tool kits of indigenous foragers and LBK people also had much in common.

Early LBK sites were well dispersed through the landscape, with large intervals between regional clusters. Settlements were small, and the majority were used only in the earliest phase. Timber longhouses were built for the outset, generally divided into two and even three sections. As yet, early cemeteries are not known.

In the middle period, settlement extended to the main limits of the loess soil and to the edge of and parts of the northern European plain. Within areas already occupied, settlements became more numerous. Burial grounds are also known in most areas. In the late phase, settlement was further extended, for example, the Paris basin and central Poland. Pottery styles became increasingly regionalized, and there may have been long-distance context with the central-western Mediterranean.

Soon after 5000 BC, different cultural groups are found in the same LBK area, such as the Lengyel, *Stichbandkeramik*, and Villeneuve-Saint-Germain cultures. Longhouses remained in use, although their shape and construction changed. The dead were disposed of in and around the settlement area. There is

also a noted increase in ditched enclosures and the formalization of space.

Britain remains one of the most intriguing Neolithic cultures. Traditionally considered as homogeneous, recent scholarship has shown great regional diversity. Moreover, it is often difficult to distinguish between domestic sites and enclosures. Northern Britain and Ireland present a picture of small social units, mostly farmsteads, scattered across the landscape. Most of the evidence for early farming is based on stock rearing rather than grain.

The Mediterranean and Its Islands

The biography of the Mediterranean is very different. The diversity within this area is intimately tied to the Mediterranean Sea. The Neolithic “package” was adopted slowly in the central and western Mediterranean. Stratigraphic sequences from caves in mainland Italy and Sicily show a mix of foraging and farming from about the early fifth millennium BC, but non-cave, ditched settlements in the Tavoliere date to almost 1,000 years later. The general impression is of mostly nonsedentary communities that combined foraging and farming. Similar trends can be discerned in southern France and coastal Spain, and perhaps in North Africa.

By 5800 BC, most of southern Italy was Neolithic, although the earlier Impressed Ware cultures survived in enclaves, such as Liguria. Moreover, although the Neolithic reached Sardinia and Corsica by 5500 BC, foragers were still present in the central Apennines, and Neolithization occurred by 5000 BC.

Southern France shares similarities with Italy, such as a lack of Mesolithic sites and sparse Mesolithic populations. The majority of Neolithic sites are caves and open settlements (mostly lost to a rise in sea level). Hunting was incorporated more in France than in Italy.

Iberia also shows a preponderance for coastal sites, and by 5500 BC, there is rapid expansion, including Portugal and Gibraltar. The interior experienced the Neolithic by 5000 BC, and foragers remained on the Cantabrian coast by 4700 BC.

Islands expressed the Neolithic in different ways. Although islands like Sardinia and Malta show plenty of evidence for extrainsular contacts, they developed their own distinct cultures. Sardinia exhibits increasing complexity from the early Cardial phases to the Middle Neolithic, which is characterized by plenty of

villages in the fertile Campidano plain. Distinct regionalism is present by the Late Neolithic. Whereas the San Michele d'Ozieri culture spread over large parts of the island, Gallura developed its own distinct stone-circle culture.

On the other hand, the small island of Malta seems to have been first colonized by Sicilian farmers in 5000 BC. As the Neolithic developed, the island gave birth to a very complex megalithic culture expressed by temples and underground funerary structures.

Monumentality

Finally, the Neolithic is often associated with monumentality, such as the causewayed enclosures of Britain and the megalithic temples of Malta. Both have been the subject of intensive studies.

The monument phenomenon has been explained in terms of chiefdom societies; territorial delineation; ostentation; and, following Richard Bradley, forming a new sense of time and space. Indeed, the study of monuments entered a new phase in the 1990s with the application of phenomenological theory.

Mortuary mounds in Europe are frequently tied to the importance of ancestry and communities establishing a claim to agricultural land. However, the first mounds typically contained a single individual; only later did they contain multiple burials. Bradley notes that it was at that point that the monument permitted access between the living and the dead.

Causewayed enclosures became the focus for special deposits of artifacts and bones. At the same time, settlement (in the orthodox sense) became more scattered and ephemeral. Early enclosures do not exhibit many common elements, although there is a trend for them to be closely integrated into the pattern of settlement. Over time, earthworks were increasingly constructed toward the margins of settled landscape, and instead of occupation sites, they became centers for feasting and ritual activity.

On the other hand, the megalithic temples of Malta do not exhibit signs of being used as settlements. Billed as the first freestanding stone buildings in the world, they are the remains of a remarkable civilization that, until the beginning of this phenomenon, was not that different from other Mediterranean societies.

These monuments have a number of elements. They are approached across an oval space, and the

forecourt is overlooked by a façade and is composed of a row of orthostats. The side and rear walls are also built of orthostats. The inside of the temples varies greatly, but all have a number of apses. Materially, they have yielded animal (but no human) remains, obsidian, tools, and an array of statuary. Burial was initially in rock-cut graves, but as temple society developed, it was transferred to necropoli. Two are known. The first is a monumental, underground structure known as the Saflieni Hypogeum, and the second is the Brochtorff Stone Circle at Xaghra.

In conclusion, the Neolithic world is a complex and varied one, and it would be fallacious to consider Neolithic cultures as a monolithic whole. Although elements of the Neolithic “package” are common to many areas, when and how these appear and how they are negotiated are vastly different. The Neolithic is a time of the creation of new worlds and the creation and renegotiation of various identities.

The end of the Neolithic is equally contentious. Southeastern Europe is embroiled in an Indo-European controversy, and for a long while, the invasion hypothesis was favored for much of Europe. Perhaps the epochalistic Three Age system does not always express the complexities of any period. The impression of a clean, definite break between one epoch and the other is often misleading. There is still much scope for research into this period, bearing in mind that we do not have one Neolithic but many.

Neurotheology is the scientific study of religious or spiritual experiences and feelings. By using psychology and neuroscience, scientists explore the biological basis of religious experiences and are beginning to uncover the capabilities of the human mind. Neurologists have found evidence in the mechanics of the human brain that facilitates the capacity for spiritual, religious, or mystical experience and leads to an intermingling of science and religion. Neurotheology claims that the hardwiring of the human brain not only makes religion possible, but also makes it capable of being passed on through the genes as a physically distinct mechanism of cultural transmission, allowing religion to be selected as an adaptive behavior.

Religion has contributed to human evolution and continues to be a universal behavior even in apparently scientific times. In fact, statistics show that 70% of the world's population affiliate themselves with some religious or spiritual practice, whether they engage regularly or not.

It is important to understand what is meant by religious, mystical, or spiritual experience. It is the universal, transcendental state described by many as a feeling of being at one with the world, their God, everyone, or themselves, depending on the vocabulary of the religion with which they are affiliated. It often involves a period of deep concentration that is termed meditation or prayer by some religions, but also has been known to happen spontaneously to those without conventional religious belief. This would lead one to believe that it is in the potential of all human brains to have a mystical experience, not just those using religious vocabulary to describe it. Studies show that the potential of each person lies in his or her willingness to let the experience happen.

To understand how the human brain could possibly be wired for the internal mystical experiences of religion, we must first understand how our brain works to interpret our surrounding environment. The brain has several association areas in the cerebral cortex that are designed to put together all of the perceptions our other sensory organs experience. The ultimate goal of these areas is to help us understand the world around us and decide on specific responses.

Andrew Newberg and Eugene D'Aquili believe that four association areas play an important part in

producing the potential for religious perception. The visual association area aids in our ability to visually recognize people, places, and things, allowing our memories to hold a visual composition of events or perceived events. The verbal conceptual association area allows us to generate abstract concepts and describe them with words; it is located in the temporal, parietal, and occipital lobes of the brain.

The orientation association area (OAA) and the attention association area (AAA) are the most important to religious experience. The OAA is in the posterior section of the parietal lobe and receives sensory input that creates the three-dimensional sense of body and orients the body in its surrounding space. There are two OAAs in each hemisphere of the brain that function in related but distinct fashions. The left OAA creates the sensation of a limited, physically defined body. The right OAA generates spatial coordinates that provide the body with the limits of its surroundings. The two OAAs intermingle information to create a defined body that has a definite space around it in which it can move. Because spiritual experiences involve an altered sense of the time and space in which the body or the "self" exists, the OAAs are important to the reality of the experience.

The AAA is referred to as the seat of the will and is in the prefrontal cortex of the brain. It is involved in the complex choreography of integrating bodily movements and behaviors associated with reaching goals. From the seemingly simple task of reaching for an object to the laborious thought process involved in deep concentration or focus, function is therefore a main factor in the experience of transcendental states of being.

To test their claims, Newberg and D'Aquili's research involved the study of deep meditation. For the experiment, a Buddhist sits in a dark room setting up his ritual meditation scene. Candles, incense, and a picture of his deity are all important to the mood and thus important to the experience that the subject will have. Newberg and D'Aquili state that the acts of rituals themselves are the first steps in preparing the brain to be open to a transcendental experience.

The subject sits in meditation position, and a piece of string stretches into another room, where the doctors wait for a signal, a tug on the string that the "peak" state of meditation has been achieved. When the string is tugged, the doctors inject a radioactive tracer solution into an I.V. that has been placed in the subject's left arm. Because the solution goes directly

into the bloodstream, it “locks” onto the brain cells almost immediately and will stay there for hours.

The meditation session is quickly ended, and the doctors move the subject to another area of the hospital where a single emission computed tomography (SPECT) camera is located. The SPECT is an imaging tool that will detect the radioactive tracer in order to photograph the peak of the meditation experience. The imaging will give the doctors a freeze-frame of the brain.

Because increased blood flow to an area of the brain represents higher activity levels, this photograph will show what areas of the brain are active during meditation. What shows up is unusual activity in the posterior superior parietal lobe, or OAA. Remember that this is the area that helps us to determine which end is up and the physical limits of the self. People who suffer injuries to this area would have difficulty maneuvering in their physical surroundings. They are unable to tell where things begin and end, particularly because they cannot conceive of their own physical limits.

A brain scan taken before meditation showed normal, furious activity all over the subject’s brain, which shows up in vibrant bursts of reds and yellows. The peak scan, however, shows markedly reduced activity in the area of the OAA, which shows up as cool blues and greens. Normally, this area never rests. Newberg and D’Aquili have come to the conclusion that the OAA is working as hard as ever. What has changed is the sensory perception of the outside environment. The incoming flow of sensory information essentially has been blocked by a deep state of concentration inward. The OAA has no incoming information with which to define the limits of the self, and while continuing to search for this information, the brain perceives no distinctions between the limits of the self and the physical boundaries of the outside world. The brain perceives the self as endless. To the subject, this experience is unquestionably real.

Newberg and D’Aquili also researched several Franciscan nuns during prayer. The SPECT scans of the nuns revealed similar changes in brain activity. Unlike the Buddhist’s feelings of oneness with the world, however, the Sisters tended to describe their experience as closeness to God. The doctors describe both experiences as absorption of the self into something larger and conclude that the mystical experiences are scientifically observable, neurological events that are experientially and biologically real.

What Newberg and D’Aquili believe they have found is the core of neurotheology, the evolved biological link to spirituality that has the ability to be passed on through genes. We hold a physical memory of our past in our genes and an implicit and explicit heritage in our cultures, languages, and moral and religious traditions that are passed on by our brains and our books. To realize the co-evolution of culture and biology is important to the perpetuation of religion and availability to mystical interpretation of the transcendental experience. Newberg, D’Aquili, and others claim that humans are naturally equipped to induce effortless self-transcendence. They describe such everyday experiences as being moved by music or the feeling of being swept away by an inspirational speech as examples of everyone’s potential for transcendence.

Neurologists have previously found a connection between temporal lobe epilepsy and new interest in religion. It is during seizures involving this portion of the brain and those of the association areas that patients describe religious experiences occurring. When the electrical impulse of a seizure disturbs areas of the brain, hallucinations, voices, and feeling of a presence or infinite space occur, creating an imitation enlightenment.

In fact, with this discovery, it is believed that many religious and historically significant individuals actually suffered from temporal lobe epilepsy. For instance, Joan of Arc, a historic woman who led the French army against the English with her perceived voices and visions of God, is now believed to have suffered from temporal lobe epilepsy. The condition would have caused her to hear her own conscious thoughts as if they were coming from an outside entity. She also described bright lights and hallucinations, which are known to be symptoms of temporal lobe epilepsy.

It is also speculated that Moses, a prominent prophet in one of the world’s most popular religions, was afflicted with temporal lobe epilepsy. His visions of the Archangel Michael led the Israelites out of Egypt and are the basis for a portion of the Old Testament.

The affliction of imitated enlightenment is not seen only in historical accounts. Psychologist Dr. Oliver Sacks encountered a patient in the early 1970s named Greg F. Greg was in his early 20s when he joined the Hare Krishna, a religious group. Shortly after taking up residence in the main Krishna temple in New Orleans, Greg began to lose his vision and experience

a glazed-over feeling. The Krishna interpreted this as Greg's path toward spiritual enlightenment. However, when his parents came to visit him 3 years later, their once-healthy young man was now a bald, fat, 25-year-old man with a huge midline brain tumor. Greg was able to have surgery to remove the tumor, but he never recovered his vision and remained forever blissed out.

Richard Dawkins sees religion in terms of pathology. He considered the God-meme (a unit of culture) a virus that infects an organism and produces copies. Susan Blackmore, referring to religious laws about killing nonbelievers, describes religion as a way that "even evil and cruelty can be redefined as good." Religion itself and its practices are not always as beneficial. For example, being involved in a doomsday cult and participating in mass suicide would not improve anyone's inclusive fitness. There is also evidence of psychological damage wrought by dogmas of guilt and fear. And, some religions allow the blatant physical and psychological abuse of women, including genital mutilation. Historical accounts describe hundreds of years of Holy War and the persecution of people because of their faith or lack thereof. Even today, in a scientifically modern world, some religions justify the killing of people throughout the world. Religion has, however, persisted for thousands of years, and there must be adaptive benefits resulting from it.

One benefit that has long been known in the East is that meditation has health benefits. Physical benefits to the body include a reduced heart rate, lower blood pressure, and decreased levels of stress hormones that would inhibit the immune system. These benefits seem to transcend religious affiliation. Religion appears to generally increase longevity, which in turn increases relative fitness.

While some see religion's persistence as self-delusional superstition, others believe it still exists for healthier reasons. Studies suggest that people who are affiliated with and practice a religion have fewer strokes and heart attacks, and lower blood pressure. Newberg believes that religion bonds families and individuals, providing them with unifying beliefs. It encourages more peaceful and productive community settings. Clearly, the benefits of religion would give those inclined an advantage in the evolutionary struggle for survival.

However, the benefits of religion are not always outwardly apparent. What would the benefits of

religion have been to our ancestral cousins that would have allowed it to continue to be selected for? Even today, like in the past, religion brings people together with a sense of community. Within this community, it is less likely that you will go hungry or be without shelter or care when you are ill. There is evidence, though disputed in Neandertal burials, of osteoporosis and arthritis, suggesting that they took care of their elderly and enfeebled.

In the past, environmental stress would have been difficult to understand. Indeed, it was in times of famine that ancient Native Americans created deities such as the Great Stag, to whom they prayed for increased deer populations. Newberg describes a speculative but interesting scenario in which a hunter is out searching for deer for days with no food or water and begins to hallucinate of a talking deer. After returning to the village and telling his story, some other hunters also return with an excellent amount of meat, which the Great Stag had foretold in the hallucination. Whether the benefits are coincidental or divine intervention, it is easy to see how the hardwiring of the human brain could have created and perpetuated the mystical experiences that led to the development of hundreds of religions and vast interpretations of transcendental episodes.

As far as Newberg and D'Aquili are concerned, religion has been around since before modern *Homo sapiens*. However, they do not think that the hardwiring used to genetically transmit potential for religious experience evolved specifically for this purpose. In fact, Newberg and D'Aquili have hypothesized that the potential for religion is actually a by-product, having risen from the circuitry involved in mating and sexual experience. They state the vocabulary of mystical experiences of the past as part of their evidence. Such words as *bliss*, *rapture*, *ecstasy*, and *exaltation* have been used to describe transcendental experiences and sexual experiences alike. "Mystics speak of losing themselves in a sublime sense of union, of melting into elation and of the total satisfaction of desires."

This theory is also based on the fact that many of the areas of the brain involved in transcendence are also involved in sexual arousal and the connection to the powerful sensation of orgasm. A similar blocking off of outside senses is experienced in both situations. They are not the same experience, just functioning on some of the same neural pathways. Falling in love involves the same sense of reception to the experience as the potential for a transcendental experience.

That religion is a by-product does not necessarily lessen the experience. Many of the brain's most sophisticated functions evolved from more humble beginnings. For instance, the ability to appreciate music and art developed from simple survival tasks. For religion, evolution stumbled in the right direction and took hold, continuing to allow the biological and cultural facets to co-evolve.

The way that we perceive our surrounding environment lays in the inner workings of the brain. The evolution of the concept of self led to the distinction between mind and brain, leading humans to contemplate more than where their next meal was coming from. Neurotheology does not claim to either support or deny the existence (now or in the past) of one all-knowing God, as believed in many religions. It does, however, thoroughly demonstrate the ability of the human brain to create and therefore experience religious, mystical, or spiritual experiences.

NGANDONG

Ngandong is an archaeological site located on the High Terrace deposits near the Solo River in eastern Java, Indonesia, that includes remains of early *Homo sapiens*. Excavations of the site were conducted between 1931 and 1933 by Eugene Dubois.

Originally called *Homo solonesis*, or “Solo Man,” the remains were thought to belong to a more advanced population than *Homo erectus*. Remains found at the site include 13 skull caps. Of the 13 crania or cranial fragments, nine are adults or at least

fully grown, and one is clearly a child. Additional finds include two fragmentary tibia bones. These indicate that one individual was 167 cm and the other 188 cm tall, which is larger than other finds of early *Homo sapiens* in Indonesia. The general impression of the Ngandong hominids is that they were a very powerful and muscular people. This is indicated by the bony evidence of muscle attachments, as well as in the form and thickness of the bones themselves. The specimens were not intentionally buried, and there are no archaeological associations found directly with these remains. Healed cranium wounds were common in the Ngandong specimens and are found more on presumed female than male crania.

Most of the crania were faceless and/or baseless, and it is uncertain whether this was the result of ritual treatment of the dead, taphonomical factors, or perhaps preferences of those who collected the specimens. Some even suggested that they were used as water bowls. The most probable explanation, however, is that the face and base contain the most fragile bones of the skull, and either the action of carnivores or natural damage through the process of fossilization led to the destruction of these parts.

Found near the broken crania was a fossil bed of 23,000 mammalian bones, mostly of extinct elephants, oxen, and hippos. Along with the mammal remains, an assortment of scrapers, borers, choppers, and stone balls for use as slings was found. Evidence that these early *H. sapiens* had social organization and used simple tools is supported by these findings.

Previously, it was thought that the Ngandong remains dated to about 100,000–250,000 years ago. But recently, teams have reexamined the Ngandong excavations using electron spin resonance and mass spectrometric uranium-series techniques to reach a date as recent as 43,000–27,000 years ago.

The Ngandong hominids are considered by most authorities to be ancestral to modern Australian Aborigines. The date of the earliest hominids in it is in dispute, but most authorities would agree that Australia has been occupied by humans for at least the past 120,000 years. If this is the case, then the Ngandong population cannot be ancestral to the Australian Aborigines.

NIETZSCHE, FRIEDRICH (1844–1900)

The German thinker Friedrich Nietzsche presented scathing criticisms of the human sociocultural world (particularly religion and theology) and called for a rigorous reevaluation of all values. Like Darwin, Nietzsche presented a dynamic view of reality. The philosopher had been greatly influenced by the evolutionary movement of the 19th century (although the intellectual relationship between Darwin and Nietzsche is not often emphasized or recognized).

Nietzsche is often referred to as the bold father of atheistic existentialism, a severe critic of science and reason, and even an early postmodernist. But if one comprehensively examines his worldview, it then becomes apparent that Nietzsche was also a philosopher of evolution (although he disagreed with Darwin's interpretation of biological history). And despite his perspectivism, Nietzsche never rejected science and reason outright; surely he thought that some theories are closer to the truth than others, and for him evolution was a fact on all levels of reality. He also looked at the human condition from a cross-cultural perspective, thereby anticipating the ongoing anthropological framework that emerged in the 20th century.

Early Evolutionists

Darwin was troubled by the issues that were raised by his theory of evolution, particularly questions concerning the place of emerging humankind in

planetary history. Evolution challenged the alleged uniqueness of our species, and it drew more attention to the existence of evil in the world. Furthermore, Darwinism did not support order or design or teleology in organic evolution. Darwin's early interest in natural theology had been replaced by natural science.

Actually, Darwin himself never defended his theory in public, and he rarely answered his critics in print. Fortunately, two famous naturalists were eager to defend Darwinian evolution: Thomas Huxley in England and Ernst Haeckel in Germany. To further support scientific evolution, Huxley contributed evidence from his studies in comparative morphology, while Haeckel offered evidence from his research in comparative embryology.

Unfortunately, the early evolutionists did not know the correct age of the earth or the true mechanisms of inheritance. Moreover, no fossil hominid evidence had yet been found outside of Europe to clearly demonstrate the evolution of our own species. But during the 20th century, significant advances in science and technology, as well as momentous discoveries in genetics and anthropology, would answer many of those perplexing questions raised by the early evolutionists.

Still, before the end of the 19th century there were a few philosophers who accepted the fact of evolution. One in particular did not hesitate to seriously consider both the ethical and cosmological aspects of evolutionism as he saw them. Enter Nietzsche.

Friedrich Wilhelm Nietzsche has emerged as the most influential philosopher of the last 100 years, although both controversy and confusion surround his life and thought. He was born on October 15, 1844 at Röcken in Saxony, Germany. His father, Karl Ludwig, a Lutheran pastor, died when Nietzsche was only five years old. Consequently, the precocious boy was raised in a household of females: his mother, sister, two aunts, and a grandmother.

The young Nietzsche enjoyed music and poetry. Later, his academic research shifted from theology through philology to philosophy. He developed an intense interest in classical Greek culture (especially the ideas of Heraclitus) and interpreted artistic expression as the synthesis of Apollonian individuality with Dionysian creativity.

dissertation. After ten years, because of poor health and grave illness, he resigned his teaching position and, with a pension, became a solitary wanderer in the Alps of Italy and Switzerland. He remained isolated and lonely but authored remarkably prophetic and intellectually profound works of lasting significance.

With time to think and write, Nietzsche critically analyzed Western civilization and revealed the falsehoods and illusions that were pervasive within the conformity and mediocrity of modern society (as he saw it). He boldly proclaimed that “God is dead” and subsequently called for a rigorous reevaluation of all values. His penetrating genius not only distinguished between the “master morality” of creative individuals and the “slave morality” of the inept masses, but also contributed disquieting insights into the psychological motives of Christian beliefs and religious practices, for example, guilt, pity, and resentment.

Nietzsche was deeply concerned with what constitutes the “good life” for a human being and, as an existentialist, he stressed that self-fulfillment ought to

be the goal of any creative and critical person who is challenged to overcome the pervasive conflicts in both the natural and social environments.

Nietzsche presented three remarkable ideas: the will to power, the future overman, and the eternal recurrence of the same.

Rejecting nihilism and pessimism, Nietzsche offered a radically new worldview that was optimistic and in step with the evolutionary movement of the 19th century. He held dynamic reality to be essentially the will to power and prophesied the coming of the overman (seeing the human species as a temporary link between the fossil apes of the past and those superior intellects that will emerge in the future).

In terms of metaphysics, Nietzsche taught his awe-inspiring and engaging concept of the eternal recurrence of the same as the endless and identical repetition of this finite and cyclical universe throughout all time. Essentially, the German philosopher emulated those pre-Socratic thinkers who had focused their attention on cosmological issues. Concerning ethics, Kant’s universalization of a free moral decision is transformed into Nietzsche’s eternalization of a seemingly free personal choice. As a result, Nietzsche claimed that each moment has infinite value and therefore one should live as if each decision is a choice made for eternity. In fact, he stressed that one should even love the pervasive necessity of determined reality.

Among his brilliant books, Nietzsche’s major work, *Thus Spake Zarathustra* (1883–1885), best represents his iconoclastic philosophy of perspectivism, overcoming, and fulfillment. With piercing insights, its author examined the human condition and found it to be oppressed by outmoded beliefs, narrow perspectives, and false values. His own emerging atheistic, this-worldly, and life-affirming vision challenges an individual to accept the endless flux of nature and to create new values beyond traditional conceptions of good and evil.

Scientific Evolution

The scientist Charles Darwin had awakened the philosopher Friedrich Nietzsche from his dogmatic slumber by the realization that throughout organic history, no species is immutable (including human-kind). Pervasive change replaced eternal fixity.

Darwin had embraced the facts, concepts, and perspectives in historical geology, comparative paleontology, and biogeography. For him, the “struggle for

existence” in the living world always results in organic evolution by natural selection or the extinction of species due to their inadaptability. Although his scientific interpretation was mechanistic and materialistic, he himself did not get involved with the profound existential issues raised by this new worldview.

Darwin was not a philosopher. He did not concern himself with those questions that deal with the meaning and purpose of life on earth. Issues in ethics, metaphysics, and epistemology did not deter him in his rigorous investigations into the mechanisms of and evidences for organic evolution. No doubt, Darwin the scientist would have found Nietzsche’s philosophical speculations on life to be both incredible and inconsequential. But, if evolution is true, then what are the scientific implications, philosophical ramifications, and theological consequences for taking this brute fact of dynamic nature seriously?

Going beyond Darwin, Nietzsche offered a bold and provocative interpretation of dynamic nature that considered both the philosophical ramifications and theological consequences of taking the scientific fact of biological evolution seriously.

Clearly, Nietzsche was not oblivious to either geological time or the paleontological record. He accepted the most controversial implication of Darwin’s theory: humankind had evolved from remote apelike ancestors, in a completely naturalistic way, through a process of chance and necessity (fortuitous random variations appearing in, and inevitable natural selection acting on, individuals in a changing environment). Even the mental faculties of human beings, including love and reason, were acquired during the course of evolutionary ascent from earlier primate forms. Of course, this position rejected the traditional dualistic interpretation of our species as mind and body, and made clinging to a dogmatic ethical principle or a fixed set of values impossible. One is reminded of John Dewey’s interest in evolving values, although he could never accept Nietzsche’s focus on the value of an individual instead of the value of a community of inquirers.

For Nietzsche, evolution is the correct explanation for organic history, but it results in a disastrous picture of reality, since evolution (as he saw it) has far-reaching truths for both scientific cosmology and philosophical anthropology: God is no longer necessary to account for either the existence of this universe or the emergence of our human species from prehistoric animals. In fact, this philosopher held

that Darwinian evolution led to a collapse of all traditional values, because both objective meaning and spiritual purpose for humankind had vanished from interpretations of reality (and consequently, there can be no fixed or certain morality).

Nietzsche knew that the previous philosophical systems from Plato and Aristotle to Kant and Hegel were inadequate to deal with the crisis of evolution. As a result, a totally new philosophy of the world was now required. So, Nietzsche offered an interpretation of reality that accepted the fluidity of nature, species, ideas, beliefs, and values. Furthermore, he held that it is nonsense to think that the fact of evolution can ever be taught as if it were a religion (since, for him, the process of evolution contains nothing that is stable or eternal or spiritual). Consequently, he would have rejected theistic evolution as an unsuccessful reconciliation of science with religion.

One can imagine Nietzsche’s tirades against the biblical fundamentalism and religious creationism that continue to threaten science and reason. An unabashed atheist, Nietzsche would have also abhorred Stephen J. Gould for upholding an unwarranted dualistic ontology that supports both the natural world of the scientist and the transcendent realm of the theologian. Instead, as a monist, Nietzsche would have admired Richard Dawkins and Daniel C. Dennett for their strictly naturalistic framework, which gives no credence to supernaturalism or spiritualism.

Nietzsche had assumed that the result of Darwinian evolution could only account for the success of inferior (weak and mediocre) forms of life simply in terms of sheer numbers, for example, the ubiquitous viruses, bacteria, insects, and fishes. The philosopher argued that Darwin’s blind species-struggle of the masses for existence needed to be replaced by his own discovery of the individual struggle by a few for self-creation and excellence.

Nietzsche saw the explanatory mechanism of natural selection as merely accounting for the quantity of species within organic history, but (for him) it is a vitalistic force that increases the quality of life forms throughout progressive biological evolution. He held that nature is essentially the will to power. Evolving life is not merely the Malthusian “struggle for existence,” but, more importantly, it is the ongoing striving toward ever-greater complexity, diversity, multiplicity, and creativity. In short, reminiscent of the interpretations offered by Lamarck, Henri Bergson, and Pierre Teilhard de Chardin (among others), Nietzsche’s

pervasive vitalism had substituted Darwin's adaptive fitness with creative power.

The philosopher held that the evolution of organisms had its origin in primordial slime, but the human species now stands high and proud on top of the pyramid of life. Even so, he saw a natural tendency for the human animal to evolve toward common mediocrity. But, through the will to power, superior individuals have the potential to master their lives (overcoming nihilism, conformity, and pessimism), as well as the intellect to actualize creative activity.

Philosophical Anthropology

As with Thomas Huxley, Ernst Haeckel, and Darwin himself, Nietzsche taught the historical continuity between human beings and other animals (especially the chimpanzees). However, the philosopher as elitist did assert that some individuals will rise far above the beasts, including the human species, but this will only occur in the remote future with the emergence of the noble overman.

If humans have ascended from the fossil apes, then why should they not be followed by an even higher form of life (as the ape has been surpassed by the human animal of today)? According to Nietzsche, the human biological species is the meaning and purpose of the earth so far, because it is the arrow pointing from the past ape to the future overman. But what is an overman? This exalted but unimaginable being will be as intellectually advanced beyond the present human animal as our species of today is biologically advanced beyond the lowly worm.

For Nietzsche, the aesthetic evolutionist as sculptor, the coming overman is like an ideal image sleeping in a crude rock. In carving out this superior being, the philosopher was guided by its shadow, although he remained indifferent to the destruction resulting from his intense creativity: "Fragments fly from the stone; what is that to me?"

Unlike the silenced priest Pierre Teilhard de Chardin, a geopaleontologist and Jesuit mystic, Nietzsche did not foresee a final end-goal or an ultimate omega point for human evolution. Instead, the finite becomes infinite. Nietzsche's metaphysics is grounded in the colossal idea of an eternal recurrence of this same universe, that is, an infinite series of identical finite cosmic cycles. Although there is organic evolution on earth within each cycle, there is no progressive evolution from universe to universe.

Consequently, Nietzsche's process cosmology represents being as becoming, and its teleological evolution from primordial slime to the future overman within each cycle is strictly determined. In the future, the noble and radiant overman will accept the eternal recurrence of the same, with its existential consequence being the affirmation of life as it was, is now, and always will be.

Reflecting on the immediate future, Nietzsche foresaw horrific wars due to conflicts of interests. Nevertheless, he himself was always optimistic that at least some gifted individuals would surmount the trials and tribulations of the human condition. The quintessential value of our advancing species (as he saw it) lies in its superior artists, philosophers, and scientists.

Nietzsche did not speculate on life or intelligence or evolution elsewhere in this universe. Furthermore, this philosopher could not have imagined mass extinctions, nanotechnology, genetic engineering, artificial intelligence, and human space travel to other planets. However, continuing advances in science and technology will offer incredible possibilities for neo-life and overbeings in the ages ahead.

Nietzsche had taken time, change, and evolution seriously. He had naturalized metaphysics (ontology and cosmology), epistemology, and values. Furthermore, Nietzsche was acutely aware that this universe is totally indifferent to human existence. Yet, his philosophy presents an optimistic challenge for those individuals who are willing to follow the lightning bolts of his heroic vision.

Darwin's influence on Nietzsche is obvious, although the two geniuses offered vastly different interpretations of evolution. Nietzsche saw human creativity as the extension of creative evolution within a creative universe. Taking this dynamic perspective to its logical conclusion, he saw our species as merely a temporary link between those past (lower) apelike forms and the future (higher) overman to come. For this philosopher, the "good life" of an individual is one that overcomes problems while it devotes itself to creativity.

In Turin on January 3, 1889, while attempting to protect a horse from being beaten by its owner, Friedrich Nietzsche collapsed in the street. He was diagnosed clinically insane due to tertiary syphilis. During the next ten years, first under the care of his mother Franziska and then his sister Elisabeth, Nietzsche remained unaware of his growing reputation as a

singularly influential thinker. His genius was now silent. After his death on August 25, 1900, the teacher of eternal recurrence was buried in Röcken, the town of his birth.

In the decades and centuries to come, our understanding of and appreciation for both organic evolution and our own species will increase in light of new facts, new concepts, and new perspectives. No doubt, there will be surprising discoveries concerning the history of life and human nature. As such, science and philosophy will move far beyond both Darwin and Nietzsche, but certainly never without them.

Nomads are mobile people with no fixed settlement and whose livelihoods integrally involve frequent movement. There are many manifestations of nomadism. Perhaps the most common is pastoral nomadism, but hunter-gatherers can also be nomadic, and shifting cultivators are sometimes described as seminomadic. Throughout the world, Gypsies (and in the West, Travellers) also lead nomadic lifestyles.

For anthropologists in search of “the other,” nomads have been clearly fascinating. In this century, nomads have seen many restrictions on their livelihoods, particularly changing property rights that make temporary access to the space and resources they require problematic. Nomads’ politics and

relations with other groups have been dominated by the evolution of these contests.

In part, the conflicts reflect the fact that nomadic use and tenure of property fits uneasily within state frameworks. States have sought to settle and control populations (Maasai pastoralists in Kenya and Tanzania). They have also sought to expropriate resources perceived to be unused (Barabaig pastoralists in Tanzania). Other conflicts arise because of nomads’ antipathy with the values of modern society (the conflict between the San Bushmen and the Botswanan government) or because of long-running hostility and suspicion between them and their settled neighbors (Gypsies and Travellers in Europe). Equally, their unintensive use of space and resources and their rejection of modern values provides fertile ground for potential collaborations with conservation interests.

Pastoral Nomads

Herding in many parts of the world requires moving animals to the best pastures, particularly if herds are large. Pastures in dry and semiarid lands may be inaccessible outside the rainy season for want of water, and pastures in temperate mountains and cold regions may be closed in winter. Good herd and pasture management will require moving stock according to the availability of pasture. Nomadic pastoralism is practiced in the drier regions of Asia, the Middle East, and Africa, as well as mountainous regions of South America and Europe. There are no clear estimates of nomadic pastoralists’ numbers, but global populations could be about 30–50 million.

It is useful to distinguish between nomadic pastoralists, who can move to a wide variety of places within a given range according to the availability of pasture, and transhumant pastoralists, who move between fixed places each season. This is particularly appropriate in mountainous regions, or in less arid rangelands where precipitation is more predictable. However, providing a robust categorization of the pattern of movements is not straightforward. Within one group in one area, the type of stock moved, the herding arrangements employed, and the reciprocal access arrangements to pasture can be enormously diverse.

Pastoral nomads are generally marked by their specialized production systems, which focus principally on livestock products that are sold or exchanged for agricultural crops and other goods. Their trade and

pasturing arrangements can rely upon longstanding, but individually negotiated, exchanges. In West Africa, for example, the southerly migration of the pastoral Fulani is facilitated by arrangements with local farmers to graze their cattle on the crop residues in fields.

Pastoral nomads have faced increasing pressure on their pastures, in particular because their seasonal use is rarely well recognized in formal law. In East Africa, there is a long history of pastoralists being evicted from their lands in the face of development or conservation projects. Land titling now threatens further subdivision and possible restrictions on movement. In Mongolia, however, the collapse of collectivized agriculture has seen the revival of nomadic practices.

Hunter-Gatherers

Like pastoralists, hunter-gatherers are found in many places around the world: in arid lands, tropical forests, and the far north. Once widespread, there are now approximately 250,000 hunter-gatherers in the world. Their migration patterns reflect the need to follow migrant animals on which they depend, and to avoid excessive hunting in one place. The latter is driven by the need for a successful hunt, not by any conservation ethic.

Hunter-gatherers' diets are dominated by plants and wild foods that are collected on hunting expeditions. Although they do not generally cultivate or herd, they do regularly and deliberately alter their environments,

planting edible or medicinal crops, protecting useful trees, and burning rangelands and forest.

African anthropologists are locked into a bitter dispute as to the history of hunter-gathering. For analysts such as Marshal Sahlins, hunter-gatherers were the "original affluent society" who have little work that they must do in order to meet their needs. For Wilmsen and others, hunter-gatherers are the impoverished relations of pastoral and agricultural groups who have been forced into this livelihood after losing wealth and livestock.

Gypsies and Travellers

These nomads are found throughout the world. The most well known are the Roma, who originated in northern India, from where their language (Romani) derives. There are approximately 12 million Roma throughout the world. Romani slavery was abolished in Eastern Europe in the mid-19th century, prompting a migration to the New World. In the 20th century, some 500,000 Roma are believed to have been killed by the Nazis, and they suffered further under Ceausescu's dictatorship in Romania. Irish Travellers, or Tinkers, are a minority group of some 50,000 who live in Ireland, the United Kingdom, and the United States and are a distinct ethnic group from the Roma with their own language.

Both groups live from trade and short-term work but have long had strained relationships with settled

people, which threatens their lifestyle. Years of marginalization have enhanced their exclusion, but also their attraction to people disillusioned with mainstream society. Recently, the term *Travellers* has been applied more generally to people who live lives similar to the Roma and Tinkers, but who do not have the tradition or family history of doing so. In western Europe, Gypsies and Travellers live in caravans and are allocated marginal unwanted lands, often in unpleasant areas. Recently, British gypsies have sought to buy

land on which they rapidly construct the facilities they need for their homes, occasioning conflict with locals and planning authorities.

NON-DARWINIAN EVOLUTIONARY MECHANISMS

Charles Darwin was never entirely satisfied with the evolutionary role he originally gave to natural selection in *On the Origin of Species*. He later expressed reservations about attributing too much of evolution to the action of natural selection and survival of the fittest because he became convinced that nonfunctional structures evolving without natural selection could later prove to be useful and therefore come within the range of natural selection. Darwin thought his failure to sufficiently consider the existence of structures that are neither beneficial nor injurious was one of the greatest oversights in his work. He realized that he was not able to eliminate entirely the influence of his former belief that each species had been purposely created and each structure was of some special service. He felt that anyone with this assumption in mind would naturally extend the action of natural selection too far.

Darwin's observation on the link between natural selection and a belief in the purposeful creation of species remains applicable to much of evolutionary biology today. Evolutionary approaches in anthropology and archeology are largely reduced to imagining the evolutionary advantage conferred by an adaptation, and this presumed advantage is supposed to explain why the adaptation came into existence. In a

recent compendium on the evolution of great ape intelligence, for example, authors repeatedly imagined selection pressures that were supposed to have increased the intellectual ability of great apes compared with other primates. Because a larger and more complex brain was more costly, it had to be an advantage so that it could be selected to provide the advantages by which it would exist in the first place. Never, in any of these arguments, is there any empirical demonstration that such adaptations owed their origin to the past action of natural selection or that the advantages incurred had anything to do with their origin.

The appeal to imagined selection pressures is superficially very attractive because it requires no deeper understanding of biological structure beyond the constraints of imagination. As Darwin correctly identified, the mode of reasoning is scientifically problematic because it involves an explanation of the origin of a structure in terms of its purpose in servicing the organisms' future survival and reproductive success. Many modern practitioners of evolution appear to be unaware of Darwin's concerns, and with natural selection shown to have an ecological reality, it would seem to be a simple extrapolation to assume its role in evolution as well.

The use of teleological reasoning—the explanation of origin in terms of future purpose—is perhaps one of the greatest ironies of evolutionary biology. Evolution was supposed to end this kind of reasoning and yet it continues as the most popular and pervasive form of biological reasoning. Teleology makes nonsense of biology because it reverses the actual relationship between morphology and genetics by treating morphology as a response to a need that in turn determines the genetic basis for a feature's existence. This developmental relationship is the wrong way around because it is the pathways of molecular communication that produce morphology in the first place, and it is the organism's morphology that constrains what the organism can or cannot do. In what Jeffery Schwartz recently called the “vacuum theory of evolution and adaptation,” the biological structure or adaptation of an organism is sucked into a function, and the genetic foundations of this form are sucked along the way.

Darwin not only questioned the applicability of natural selection to evolution, he also attributed the origin of nonbeneficial structures to “laws of growth” acting independently of natural selection. The nature

of these laws was characterized as being largely unknown, although he suggested general possibilities such as “correlation,” “compensation,” and structural “pressure.” His views reflected a concept of biological organization that determined the kind of changes that could take place in the evolution and adaptation of an organism. With the widespread skepticism about natural selection among most evolutionary biologists through the late 19th and early 20th centuries, there was considerable interest in alternative models that looked to a biologically mediated process of evolution. One of the most prominent non-Darwinian models was “orthogenesis,” proposed in 1893 by William Haacke. Like many other evolutionists, Haacke noted a sequential pattern of changes in the biological structure, particularly in the fossil record. These changes suggested to Haacke that there was a biological link historically connecting the sequence of evolutionary changes. He cited the well-known example of the single-toed modern horse that did not evolve directly from a five-toed ancestor, but involved interim toe combinations. Terms such as Berg’s *nomogenesis* and Rosa’s *hologenesis* also represented similar concepts. These alternatives to natural selection encompassed the principle of organisms evolving as a consequence of their biological properties. Organisms were not passive blobs of organic jelly that sat around doing nothing until pushed by an external force such as natural selection. Rather, there were two active elements in evolution—the organism and the environment.

The combination of Mendelian and population genetics in the 1930s was seen by architects of the Darwinian synthesis to substantiate the primary role of natural selection in evolution. As selection became more popular, orthogenetic models waned under the burden of having no comparable explanatory mechanism and the problematic application of orthogenesis to teleological models by some evolutionists. Prominent Darwinian scholars such as George Gaylord Simpson, Ernst Mayr, and Stephen Jay Gould dismissed orthogenesis as an imaginary, if not a mystical, dead end, often equating the concept to the idea of “straight-line” evolution (instead of branching), even though this representation was historically incorrect. Ironically, Darwinians such as Gould and Eldredge ended up dabbling with orthogenetic ideas when they acknowledged that the origin of variation could not be entirely random because it was apparent that there were structural constraints in the type of

organization of an organism at any given time. However, unlike Darwin’s laws of growth, structural constraints were not a mechanism generating change, just a limit on the mutational possibilities that were still random and spread through the action of natural selection.

Concurrent with the Darwinian evolutionary synthesis was a distinctly non-Darwinian panbiogeographic synthesis proposed by the French-Italian biologist Leon Croizat. Whereas most evolutionary theorists focused on the origin of species in terms of their biological differentiation and adaptation, Croizat developed a theory focused on their geographic differentiation, because all species evolve in both space and time. It was geographic distribution that provided Darwin with evidence for evolution. Darwin attempted to synthesize the great problem of spatial separation between related species by proposing an original, localized birthplace or center of origin from which the species dispersed either before or after the formation of geographic barriers. This idea of geographically localized origin allowed for natural selection to affect the evolution of individual populations, and therefore speciation.

Croizat’s unique insight was to test Darwin’s theory of evolution as no one had done before, by graphically comparing distributional patterns of related taxa with each other and their dispersal ability. He found that there was no correspondence between dispersal ability and the geographic range or pattern of a group. A group of poor dispersers could be distributed as widely as a group of good dispersers. The lack of concordance between dispersal ability and distribution suggested that the location of related species in different localities was the result of their having each originated in their different localities. This vicariant origin required a different evolutionary model to that of Darwin’s centers of origin theory. Croizat suggested that vicariant species (or any other taxonomic entities) occur in different localities because the ancestor was formerly widespread and each descendant species differentiated over part of the ancestral range, giving the appearance that they had each resulted from dispersal, particularly when they may now be geographically isolated by topographical or ecological barriers. In a spatial context, the center of origin for any one vicariant species would be the entire ancestral range established during earlier geologically mediated periods of mobility.

The biogeographic process of geographically widespread differentiation involving multiple species led Croizat to propose a biological mechanism for speciation and evolution. His model was for different evolutionary trends to take place over different parts of the ancestral range as a consequence of the geographically heterogeneous distribution of ancestral characters. An ancestor with characters ($a + b + c + d \dots$) would vicariously evolve into descendants with characters ($a + b$), ($a + c$), ($b + c$), and so on, according to the geographic clustering of those characters. He also looked to biological structure and, as Gould and Eldredge noticed many years later (although Gould had read Croizat's 1958 book during graduate school), Croizat recognized that organisms represented particular types of organization that constrained and oriented the range and direction of evolution without requiring natural selection. Croizat identified the process as orthogenetic and compatible with Darwin's concept of laws of growth.

Croizat was the first evolutionist to attempt a comprehensive synthesis of orthogenesis and natural selection by viewing orthogenesis as the primary constraint upon the evolution of novelty, whereas natural selection provided fine-tuning between the structure of an organism and its environment. He also drew attention to the developmental relationship between different morphologies, such as the interchangeable positions of legs, wings, and antennae on flies, as the result of a common developmental process. These observations led to a general model of biological development that he called morphogenesis, whereby a single developmental process could be altered slightly to generate many different individual morphologies. In genetic terms, Croizat described this as the recombination of ancestral characters resulting in descendants as specialized versions of the generalized ancestor.

Despite objections by Darwinian theorists to orthogenetic models, molecular and developmental studies also point to a complex, interconnected biological foundation for the origin and evolution of variation. The geneticist Gabriel Dover (University of Leicester) and the primate systematist Jeffrey Schwartz (University of Pittsburgh) have both proposed radical departures from the general Darwinian assumption of evolution being primarily the result of natural selection acting on minute incremental changes in variation. In contrast, they emphasize the

role of regulatory genes affecting the presence or absence of entire structures or organ systems, so evolution may not require incremental missing links between different biological forms or structures (for example, the evolution of the eye may not require intermediate and incomplete ancestral eyes). Although selection may change the pattern of variation for a given structure, selection acting upon that structural variation will not make it disappear altogether.

Developmental genetics suggests that the origin of biological structure involves a web of interactions between regulatory and structural genes in which one gene can turn a variety of other genes on or off. This is not a simple relationship between particular regulatory and structural genes and a specific structure, because both master and target genes may participate in many different functions involving unrelated developmental, metabolic, and behavioral processes. With genes each contributing to a function or structure through molecular interactions with other genes and their proteins, any given gene can be involved with multiple partner genes, and it is the combination of partners in any given cell at any time during development that gives rise to a particular part of the individual organisms. No individual gene, or even complex of genes, exists uniquely for a given biological function. A given species-specific structure emerges at the right time and place when a group of multifunctional genes is active or inactive in the appropriate combination at a given location and point in time. This coincidence of gene interactions at a particular stage of development is, itself, contingent upon earlier combinations of genes that can also involve some of the same genes.

This complex and contingent relationship between regulatory and structural genes does not support the popular selection-based narratives that assume that biological structures and adaptations are the result of incremental changes in variation. Morphogenesis involves a complex relationship between regulatory and structural genes that lies outside the popular model of incremental variation and natural selection. Dover focused on the nonindependent evolution of repetitive DNA sequences called concerted evolution, which suggests that there are nonreciprocal transfers of sequence information, such as biased gene conversion, that spread mutations through an entire gene family and a sexually reproducing population. This spreading mechanism, called molecular drive, can result in a long-term change in the genetic

composition of a population, and where the gene involves multiple copies, it cannot be spread through natural selection because the mutation must convert multiple sites. As these mutations become established, a phenotypic transformation of a population may permit the organism to exploit previously inaccessible components of the environment. Schwartz looked to a Mendelian mechanism of genetic turnover involving the accumulation of recessive mutants within a population giving rise to relatively rapid evolutionary events when they reached a critical level of representation to produce a high number of homozygote individuals who could preferentially mate and produce a new lineage or allow the exploitation of different ecological relationships.

The molecular and developmental evolutionary models are non-Darwinian in the sense that they do not assume natural selection as the predominant mechanism for the spread of evolutionary novelty and adaptation. By providing an alternative biological context for evolution, the models are Darwinian in the sense that they develop Darwin's laws of growth in the context of molecular genetics and development. These models demonstrate a genetic and developmental foundation for earlier non-Darwinian orthogenetic models of evolution, and they call into question the widespread assumption that there is a functional purpose for adaptations that is the reason for their existence, or that imaginary selection pressures or advantages necessarily have anything to do with evolutionary novelty. Once selection is no longer necessary for the spread of novel mutations, the evolutionary questions shift to the origin of the mutation itself. Is the origin of any given mutation contingent in some way with preceding mutations? It is this consequence of the structural constraints inherent in each type of organization that is implicit in orthogenetic models and that remains to be explored by evolutionary biologists.

A biologically based model for the evolutionary spread of novelty reverses current models for interpreting the evolution of humans and human ancestors. For example, the evolution of bipedalism may be the result of a shifting relationship between regulatory and structural genes producing a skeletal and musculature structure that resulted in the evolution of obligate bipedalism, whether or not the ancestor was arboreal or terrestrial and whether or not these ancestors liked it. As an ecological consequence, the bipedal mode of locomotion may have decreased

exposure to radiation that allowed, in turn, for ancestral hominids to survive in open habitats. Hair loss may be necessary for effective survival of a biped in open situations through greater cooling, but it is the loss of hair that made this possible in the first place rather than the need to lose hair. Increased intelligence may have afforded hominids greater opportunities for survival, again as a consequence of changes in brain evolution, not as a cause of that evolution. The benefit is the result, not the origin, of evolution.

Even with molecular and developmental evidence suggesting a biological foundation for evolution without natural selection, it is highly unlikely that these models will gain much popularity among historical evolutionists in anthropology and paleontology. The temptation to continue to construct imaginary narratives assigning purpose to the meaning of life through untestable notions of historical selection pressures and advantages will be a temptation too hard to resist.

Norms (from Latin *norma*, a square, used by carpenters, masons, and other artificers to make their work rectangular) are either statistical or ideal. In the statistical sense, the norm is the average. In the ideal sense, however, a norm prescribes or expresses an ideal pattern or standard of behavior in a given social group or social context to which conformity is expected. Confusion between these two kinds of norms should be avoided. Under certain circumstances, it may be normal in the statistical sense to transgress norms of an ideal nature.

Cultural and social anthropology are mainly interested in ideal norms. Norms as standards of behavior

are an essential part of any culture. They provide a system of order and orientation. Nevertheless, they are subject to transformations and may differ from culture to culture. Moreover, societies develop not only several types of norms (such as folkways, mores, and laws), but also sanctions to help enforce the norms, reward conformity, and punish deviance.

One of the tasks of the cultural or social anthropologist is to describe the contexts that distinguish acts of deviance from acts of conformity in a particular community, and to reconstruct the social and cultural norms that generate such judgments. In addition, an anthropologist who works in different social or cultural contexts requires knowledge and sensitivity to social or cultural norms.

Norms, Culture, and Socialization

Ideal norms expressing standards of behavior are part of any society and culture. In many respects, humans are not genetically programmed for one pattern of behavior, but rather have the capacity to learn many different patterns. Any given society institutionalizes a specific set of behaviors selected from the wide range of possibilities. Behavior that may be seen as appropriate in one culture may be called scandalous in another. For example, gender norms define appropriate behavior for men and women. In some societies, young girls are given their own house in which they are allowed to play “wife” with boys they choose. In others, girls are not even allowed to talk to boys. Gender norms define not only appropriate sexual interaction but also behavior, even to the extent of appropriate vehicles for transportation. In many African countries, motor vehicles are driven primarily by men. In some countries, certain vehicles are even taboo for women to drive. At times, these may be motorcycles, and at others, trucks or cars.

In the socialization of (young) people to the norms of a society, most of the cultural symbol system that carries these norms is passed on without being explicitly taught.

Types of Norms: Folkways, Mores, and Laws

Social and cultural norms vary immensely regarding importance and the intensity of the reaction when they are violated.

Folkways are conventional norms of custom generally regarded as useful but not essential to society, and they

are fairly weak kinds of norms. For example, when people of Western societies who know one another meet in the street, they probably say “hello” and expect the other one to respond in kind. Likewise, people are expected to be courteous to pregnant women and to eat with a knife, fork, and spoon. Violations of these norms may bring about only mild forms of censure or punishment. One may be reprimanded or considered boorish, rude, impertinent, a nuisance, or an eccentric.

Mores are norms of custom generally regarded as more important for the welfare of a society than mere folkways. They often express high values and are associated with strong feelings of right or wrong, morality or immorality. Their violations may inspire intense reactions and some type of punishment, because violation would endanger the basic stability of a group. Examples in Western societies include the incest taboo, sexual abuse of children, and murder. Someone who violates fundamental mores will be considered socially unacceptable and may be expelled, banished, exiled, or imprisoned. In some societies, the breach of certain mores may even be met with the death penalty. Mores are set up, maintained, and enforced by public sentiment.

Laws are norms whose violation is met (by a state authority) with sanctions that are publicly acknowledged, socially approved, and—at least in principle—consistently applied. Some theorists stress the characteristic that laws must be formally chosen by a state and backed up by punishments for failure to conform to them, with particular social agencies designated to do the enforcing. The formulation of law has long been considered a defining feature of state-level societies. Many fundamental social institutions in state-level societies are bound up with a concept of law; examples include the sovereign authority to create law, courts established to try disputes, and a police power to prevent or punish illegal acts. Whether the absence of these institutions implies the absence of law has posed a fundamental problem for the anthropology of law, insofar as cross-cultural understandings of political institutions and of social control are concerned.

The *anthropology of law* describes the definitions of crimes in particular cultures and the procedures through which cases are adjudicated and remedies applied in particular communities. Some anthropologists claim that an anthropological approach to law must be relativistic in recognizing the variety of cultural settings in which lawmaking occurs. A variety

of approaches have been taken to the problem of defining the domain of law and the application of a concept of law to those societies, such as tribes, that lack clear, centralized political institutions. These approaches differ in the distinction drawn between laws and more general social norms. One solution has been to retain an essentially Western concept. This was the position of A. R. Radcliffe-Brown (1881–1955), who argued that simple societies have no law, although all have customs that are supported by sanctions. Another approach has been to merge law into the domain of custom. This view states that although norms obeyed by indigenous peoples have been refused the name of laws, customs that are fixed and generally obeyed are indistinguishable from laws. Holding this view, Bronislaw Malinowski (1884–1942) equated law with the field of effective social constraint. A third approach takes law to be culturally universal, yet distinguishable from a more general field of custom or social sanction. For E. Adamson Hoebel (1906–1993), a social norm is legal if its neglect or infraction is regularly met, in threat or in fact, by the application of physical force by an individual or a group possessing the socially recognized privilege of so acting. In this sense, the norm of traditional Inuit culture that a recidivist murderer may be executed by the kin of one of her or his victims—who seeks and obtains, in advance, community approval for this act—would constitute a legal norm. In addition to this general theoretical debate, ethnographic studies of law have been conducted. To name only two famous works, Karl N. Llewellyn (1863–1962) and Hoebel analyzed the character of Cheyenne legal reasoning in *The Cheyenne Way* (1941). And Max Gluckman (1911–1975), a South African anthropologist, provided detailed evidence regarding legal reasoning and standards of justice among the Barotse of Zambia in *The Judicial Process Among the Barotse of Northern Rhodesia* (1955). A main topic of contemporary legal ethnography of U.S. law is how difficult it is to “get justice” in light of the disempowerment on the basis of race, class, gender, or ethnic origin.

Deviance and Sanctions

The opposite of conformity to social and cultural norms is called *deviance*. Deviance includes psychopathology, crime, rebellion, or the simple violation of social conventions. An action accurately coded as a social misdemeanor—crime, rebellion, and so

on—could be coded as conformity in another. For example, there is a danger that conformity to the norms of one culture will be misinterpreted as a symptom of mental illness in another. A Hopi woman who reports conversing with her dead husband may be thought to be hallucinating by an unsophisticated Anglo-American psychiatrist, despite the fact that her behavior is highly appropriate in the Hopi context. In general, one of the ethnographic tasks of the social anthropologist is to describe the contexts that distinguish acts of deviance from acts of conformity in a particular community, and to reconstruct the social and cultural norms that generate such judgments. The study of psychopathology, in particular, is one task of medical or psychiatric anthropology.

Crimes are deviant acts that violate the legal norms of a particular community and for which there are legal remedies, such as punishment or compensation. Again, the appropriate kind of remedy may differ from culture to culture. In some East African cultures, for example, intergroup homicide is treated not as a punishable act of deviant behavior by an individual, as it is in Western societies, but as something like a debt that can be compensated through payment by the group responsible for the killing.

Rebellion is a form of deviance conspicuously antagonistic to authority or intended to overthrow a hierarchical status system. In some societies, the phenomenon of a *ritual of rebellion* can be found. In such rituals, roles are reversed, such as those of commoners and their king. Gluckman argued that such rituals serve the function of renewing the existing social order, while appearing to overthrow it. Likewise, historians of early modern Europe have examined the extent to which annual rituals like the European carnival expressed real social protest.

Sanctions are responses to both conformity and deviance. They function to maintain social order and social control by rewarding conformity and punishing deviance, thus reintegrating a society after a breach. They are based on collective norms and reflect a shared sense of wrongdoing. Negative sanctions are punishments of varying degrees, ranging from disapproval, gossip, and imprisonment to execution. Positive sanctions are reinforcements or rewards, such as words of praise, bestowal of honors, or canonization. Moreover, some theorists distinguish between formal sanctions, which are imposed by the state, and informal sanctions, which are imposed by members of a community. Respective studies have shown that

formal sanctions are used most often in urban settings and include arrest and imprisonment, whereas in rural areas, informal sanctions, such as gossip, are more prevalent. In addition, one may distinguish sanctions by whether they address the body or the psyche. Whereas physical sanctions, such as beating, bring about physical pain or pleasure, psychological ones, such as rewards, address the feelings and emotions.

For native members of a particular society or culture, their norms are usually a matter of course and, much like the rules of grammar, go unnoticed until they are violated and met with sanctions.

OAKLEY, KENNETH PAGE (1911–1981)

Kenneth Page Oakley was born on April 7, 1911 in Amersham, England. He received an undergraduate degree in geology in 1933 and a Ph.D. from University College, London in 1938. From 1935 to 1969 he was curator of paleontology at the British Museum of Natural History. While Dr. Oakley carried out research in the fields of physical anthropology, geology, and paleontology, his considerable fame today can be attributed to his practical work on a relative dating technique that relies on the differential fluorine content of fossils. Although this concept had been around since 1893 when French mineralogist A. Carnot demonstrated its utility for sorting relative ages of buried materials, the chemistry was imperfectly understood. But with the awareness that hydroxyl ions in bone apatite are replaced by groundwater-bearing fluorides to form a relatively insoluble form of fluorapatite (the same principle that is used in tooth anti-decay arguments), application of the concept became a reasonable relative dating possibility. Although early experiments with the technique had been unsuccessful, in 1947 at the Pan-African Congress on Prehistory, Oakley proposed that fluorine dating might solve the riddle of the Piltdown man (found 1911–1912), which for almost 40 years was considered by many scholars to represent the “missing link” in human evolution. In 1949, Oakley had the mandible and cranial fragments of Piltdown man tested at a government forensic science laboratory, and the results were ambiguous, suggesting that the two items were of a similar age but younger than originally thought. He voiced his concerns about the genuineness of the

fossil in the first edition of his 1949 British Museum of Natural History handbook, *Man the Toolmaker*. The decoding of the Piltdown man enigma was a team effort. In July, 1953, J. S. Weiner, a South African anthropologist and visiting researcher at Oxford, was the first to propose that Piltdown man was a hoax. Weiner reasoned that the teeth had been artificially ground and conveyed his thoughts to Oakley through Sir Wilfred Le Gros Clark of the Anatomy Department at Oxford. It was readily apparent to all concerned that if Piltdown man was a fake, the fallout from an uncoordinated release of information on the subject could have local (museum), national, and international implications. Between July and November, 1953 a second round of fluorine analyses was carried out at a government lab. The results showed that the skull and mandible were of different ages. In addition, the flint artifacts were examined by E. T. Hall of Clarendon Labs, Oxford, using X-ray fluorescence analysis. Hall found Fe-based paint on the cherts, with the exception of one that had chromate applied, which when removed looked like normal unweathered chert. Indirectly, Oakley contributed to the establishment of the Research Laboratory for Archaeology and the History of Art at Oxford and established the career of Hall, its first director. Oakley, as the chief proponent of the fluorine dating technique and spokesman for the Piltdown research group, was catapulted into the limelight in late 1953 with the official announcement of the fraud. He and his colleagues wrote numerous articles and books that gave the public a clear picture of the results. Radiocarbon dating in 1959 showed the age of the Piltdown modern human braincase to be 620 ± 100 BP (GRO 2203) and the Piltdown orangutan jawbone to be 500 ± 100 BP (GRO 2204). Oakley, over his long career, had a wide range of interests in which he published, but he is remembered

today for his fluorine dating of Piltdown man. He died on November 2, 1981.

A broad name for a class of pigment bases, ochre is a fine clay that has been deeply colored by iron oxide in the soil. The amount of iron oxide present in the soil is the largest determinant of the degree of redness of the ochre; excavations of an aboriginal mining site showed that the highest quality ochre (darkest red) contained roughly 30% iron oxide and 50–60% SiO₂. Depending on the amounts of iron oxide and trace impurities it contains, ochre can range from yellow to reddish brown. The presence of SiO₂ (quartz grains) accounts for its gritty nature.

Indigenous people all over the world, from Aborigines in Tasmania to the Cherokee in North America, mixed ochre with water or grease from animal fat to create thick pasty paints. Its relative proximity to the surface of the earth, typically in the first meter of topsoil, made excavation simple. Tools used for harvesting were constructed from local vegetation and stone; metal was not needed because of the ochre's shallow depth. Ochre-based paints, like other paints, can be applied with a variety of tools, such as brushes or one's fingers, and there is evidence that at the Pech-Merle cave in France artists used tubes to blow the paint onto the cave wall.

That the deep red paint had inherent magical properties was and is a widely held belief. The Wiradjuri, a tribe of aboriginal Australians, use red

ochre in the initiation ritual of their adolescent males. The ritual consists of two parts: during the first part, the elders symbolically kill the initiates with flaming sticks; during the second part, the initiates' bodies are marked with red ochre paint, symbolizing their birth into manhood. In tribes along the coast, adolescent females undergo their own initiation ritual. When a young woman first menstruates, she is segregated from the tribe with a group of tribeswomen who train her for her role in the tribe. After this, she is covered in red ochre and bathed; now clean, she returns to the tribe as a woman. Some aboriginal groups also used ochre paste to coat wounds. Australian aborigines covered themselves, their tools, and their weapons with ochre, as did the Beothuk Indians of Newfoundland, who were called the "Red Ochre People" by European explorers. Other North American tribes covered themselves with ochre paint, and in addition they would coat their bodies in ground hematite (ochre), producing a glistening shine. This coating had not only symbolic and magical intent, it also had the practical value of insulation. Peoples worldwide have found a variety of uses for ochre: as an artist's medium, as a body paint with status and intimidation value for warriors, in funerals and other rites of passage, and for healing and other magical purposes.

John Ogbu was a major figure in educational anthropology. The impact of his writings and his influence on hundreds of students and colleagues will be felt for decades to come. His work has been translated into numerous languages and has influenced educational debates within and beyond the field of anthropology.

Like many scholars before and since, Ogbu searched for explanations for the disproportionate rates of academic failure among ethnic minorities in the U.S. He found explanations based on “cultural differences” unconvincing, noting that some minorities manage to succeed at rates equal to or above those of white students, despite being culturally and linguistically quite different from the “mainstream.” He instead proposed that the essential factor shaping minority students’ orientation toward formal schooling was their status as either “voluntary” or “involuntary” minorities. Voluntary minorities are immigrants by choice who aspire to succeed on the terms of their host country; success may lead to cultural assimilation but is not in itself incompatible with membership in the minority group. Involuntary minorities, however, are the descendants of enslaved or colonized peoples (e.g., African Americans) who formed their collective identity in a context of oppression by the dominant group (whites). An essential element of involuntary minorities’ group identity is their oppositionality vis-à-vis the dominant group, expressed through alternative cultural practices and resistance to dominant institutions, including the school.

Ogbu stressed the importance of students’ own cultural practices and group identity to their school experience, but unlike “cultural difference” explanations of minority school failure, he situates minority students’ oppositional culture and identity in larger structures of racism and economic marginalization. According to Ogbu, as African American youth become cognizant of the “glass ceiling” limiting their economic advancement, they reject the ideology that posits educational achievement as the key to social mobility. Furthermore, since academic achievement is equated with “acting white,” it is viewed as incompatible with full cultural membership in the minority culture. Ogbu saw African Americans as a “caste-like” minority, their subordinate status enforced by dominant ideologies of contamination and inferiority, similar to those pertaining to rigid caste societies. While subject to the criticism that the U.S. racial hierarchy is in fact considerably less rigid than actual caste societies, Ogbu’s ideas are supported by research showing that many groups that are low-achieving “involuntary minorities” in their home countries become high-achieving “voluntary minorities” after migrating to the U.S. While recent theories of race and ethnicity posit such categories as considerably more fluid and arbitrary than Ogbu presents them, those same theories also support

Ogbu’s notion that dominant and subordinate identities are forged relationally in the same historical cauldron, rather than as independent cultural entities. Furthermore, the growing body of research into youth cultures has demonstrated the centrality of oppositional identities and resistant cultural practices to the lives and values of minority adolescents.

Ogbu was also a prominent voice in the debate over the role of Ebonics (African American Vernacular English) in formal education. As part of a California task force on African American education, he stressed the incompatibility between the linguistic norms of Standard English and those of African American communities. The task force and the Oakland School Board called for the educational use of Ebonics to help African American students transition to Standard English, but their position did not ultimately prevail. The Ebonics controversy spread far beyond academia to eventually engage the entire nation, evoking (but not resolving) myriad conflicts and popular misconceptions about race, language, and minority education in the United States.

At the time of his death, Ogbu was still theorizing the relationship between collective identity and cultural/linguistic boundaries, and using cross-cultural data to shed light on notions of intelligence and “scientific testing” of minorities. His interest in the influence of culture change on cognitive skills led him to examine what he called “cultural amplifiers of intelligence” (e.g., schooling, art involvement, indigenous economic activities) and their effects on cognition. Ogbu was buried in his native Nigeria.

 OHIO HOPEWELL

The 1848 publication of *Ancient Monuments of the Mississippi Valley* by Ephraim G. Squier and Edwin H. Davis marks not only the jumping-off point for American archaeology as an academic discipline but the beginning of our nation's fascination with the mounds and earthworks of central Ohio and the ancient Americans who built them. Today we call these ancient Americans the Ohio Hopewell. They flourished in the fertile landscape of the middle Ohio Valley at roughly the same time as the Golden Age of the Roman Empire.

As the focal point of their research, Squier and Davis mapped and excavated dozens of mound and earthwork sites in south central Ohio, centering on Davis's hometown of Chillicothe, Ross County. Some of the mounds they excavated, like those at Mound City (now a National Park Service site designated Hopewell Culture National Monument at Mound City), contained impressive examples of artifact styles rich with symbolism based on geometric and zoomorphic designs. Not long after their seminal publication, these two nascent archaeologists had a falling out. Unfortunately for modern Americans, a large portion of their collection was sold by Davis to the Royal British Museum in London. Even today, many of the most beautiful carved Hopewell effigy pipes and mica cutouts from sites like Mound City are displayed in London, rather than in the United States.

As is common for many Neolithic-stage populations, the Ohio Hopewell mounds contain the tombs and bodies of the honored dead (predominantly, but not exclusively, males) for whom the monuments were built. Thus, America's earliest significant attempt at academic archaeology represents a glorified form of grave robbing. Ironically, archaeology most clearly reveals its delicate balance between the humanities and social science when it uses the dead for data, as both social role and social status are often well marked in burials. Today, the excavation of ancient human remains is restricted by the Native American Graves and Repatriation Act, passed in 1991 to redress over a century of mistreatment of Native American dead by a scientific community who viewed them as nothing more than specimens. Sadly for the ancient Hopewell dead whom they disturbed, the mound excavations of Squier and Davis would most likely not have been acceptable under the provisions of this Act.

Nonetheless, their research set the stage for the next 150 years of Ohio Hopewell archaeology.

Hopewell: Culture or Cosmology?

In addition to their work at Mound City, in 1845 Squier and Davis also mapped and excavated another key Ross County site located on the north fork of Paint Creek, which we now call the Hopewell Earthworks. This mound and earthwork cluster is considered the type site and lends its name to the entirety of the Hopewell cultural phenomena. The Hopewell name comes from the family name of the landowner, Capt. M. C. Hopewell, who owned the farm during the second major excavation at the site. When Squier and Davis worked there earlier in the century, the property was owned by the Clark family, so accordingly in *Ancient Monuments* they called it Clark's Works. However, the name Hopewell certainly has a ring to it that Clark does not; so goes the serendipity of the naming of archaeological names. This second excavation was directed in 1891–1892 by archaeologist Warren K. Moorehead and was conducted during his explorations to collect artifacts for exhibition at the 1893 World's Columbian Exposition in Chicago.

The Hopewell Earthworks includes an oblong embankment that stretches lengthwise west to east along the terrace of the north fork of Paint Creek. This embankment is called the Great Enclosure. The embankment walls in the Great Enclosure are estimated to have been around 35 feet wide and upwards of 6 feet high, meaning that people on the outside could not have easily looked in upon the enclosed space. It encloses over 110 acres and has a square shaped earthwork attached to its east side, each side of which is almost exactly 850 feet in length. The Hopewell Square has openings, or gateways, located halfway down along each of its four walls, with the gateway along the west edge opening into the Great Enclosure, and an additional two openings in the northeast and southeast corners respectively. Rectangular mounds are placed across the mouth of each of the four gateways located along the midpoints of the square so that again, even as one enters this enclosure from these gateways, the entrant cannot look directly in upon the enclosed space.

Within the Great Enclosure there were at least 40 mounds ranging in size from small and inconspicuous conical mounds only a foot or two high to large and massive loaf-shaped mounds (the exact number

is impossible to know because various forms of degradation and destruction have taken place at the site, beginning with the Squier and Davis excavations). These mounds are placed throughout the enclosure in no apparent pattern, although some archaeologists believe there is significant symbolism in their placement and that alignments are linked to astronomical phenomena. The largest loaf-shaped mound in the Great Enclosure is a tripartite, conjoined, multi-layered mound labeled Mound 25. The mound itself was encircled by a low D-shaped embankment approximately 2000 feet in circumference, which had the straight side of the D located along the north edge. The immensity of Mound 25 is difficult to convey. At an estimated size of just over 30 feet tall, 550 feet long, and 180 feet wide (equivalent to three stories high and three city blocks long), it is by far the largest of all of the Ohio Hopewell mounds. Mound 25 is also one of the two largest man-made earthen structures in North America, being surpassed only by Monk's Mound, which is located near St. Louis, Missouri at the site of Cahokia, a large Mississippian center that may represent the only urban site in North America. Dating to the 9th–11th centuries, Cahokia was almost 600 years later than Hopewell.

Mound 25 at the Hopewell Earthworks is at the heart of what many archaeologists mean when they use the term Hopewell. It contains the most impressive burials, altars, and artifact deposits, in terms of both quantity and quality, of all of the Hopewell mounds, in Ohio and beyond. The mound and its remains appear, at many levels, to represent the ideological or cosmological center of the Hopewell world. It is important to note that the mound covers the remains of a large, multi-roomed, wooden structure, on the floor of which were buried the Hopewell dead. This structure was undoubtedly the location of the critical social interactions and expressions of ritual knowledge that define Hopewell cosmology. The mound-building activities not only closed the use of this structure but put an end to the use of the ritual knowledge in this location, making Mound 25 a monument.

The term *Hopewell* was first used to represent a prehistoric culture at the turn of the 20th century. The term was popularized following analysis and

synthesis of Moorehead's collections and in association with other major mound and earthwork excavations that had taken place in south central Ohio up to that time, including the third and final major expedition at the Hopewell Earthworks led in 1922–1925 by Ohio Historical Society archaeologist Henry C. Shetrone. However, exactly what is meant by the cultural term Hopewell has undergone considerable revision and refinement since its inception. Likewise, the term *Ohio Hopewell* now has a specific meaning of its own too, independent of the broader concept of Hopewell. Originally, Hopewell was confined to Ohio (i.e., Hopewell = Ohio Hopewell in modern terminology), but mound excavations in other parts of the Eastern Woodlands clearly showed a broad similarity with the archaeological remains excavated in Ohio. The core area in Ohio, centering on the Chillicothe region, is also sometimes referred to as Scioto Hopewell in the literature, although herein Ohio Hopewell is used as the more inclusive cultural term.

Archaeologist Joseph Caldwell proposed a concept in the 1950s that he called the Hopewell Interaction Sphere to link these widespread mound-building traditions together. However, instead of a monolithic Eastern Woodlands culture, Caldwell viewed Hopewell as a pan-Eastern ideology or cosmology, centering on

the rituals of mortuary ceremonialism. The Hopewell Interaction Sphere functioned as an exchange network that moved the raw materials and finished symbolic artifacts deposited in the mounds with the dead, but more importantly, it moved the ideology that grounded these customs. Thus, as a result of Caldwell's contribution to Hopewellian studies, regional "cultures," traditions, or phases within Hopewell emerged. Current research suggests a broadly similar time frame for all of these regional groups, which are now encompassed within what is known as the Middle Woodland period, approximately 2200 to 1600 years before present (B.P.), or 200 BC. to AD. 400.

Next to Ohio Hopewell, the Havana Hopewell, centered in the Illinois River Valley, appears to be another significant regional expression during the Middle Woodland period. Including these two important core areas in Ohio and Illinois, at least 12–18 Hopewellian regional cultures are spread throughout the south as far as Florida, along the Mississippi River corridor from Louisiana to Wisconsin, out the Missouri River as far west as Kansas City, across the upper Midwest, and into the Ohio River Valley as far northeast as the Upper Great Lakes in upstate New York. Conservatively, it has been estimated that there were over 20,000 mounds erected by Eastern Woodland peoples over the span of about 1500 years. Yet, with few exceptions, Ohio is the primary location of the Hopewell earthwork-building tradition, especially of the large geometric variety like the Hopewell Square and the complex geometric constructions at Newark, Ohio, in Licking County, which included an octagonal earthwork attached to a large circle (large enough to encompass an 18-hole private golf course, which has been rented in perpetuity from the Ohio Historical Society), another large circle, two large squares, several small circles, an elliptical enclosure, dozens of mounds, and miles of parallel embankments linking the complex together.

Origins

The origins of the Hopewellian mortuary ritual ceremonialism can be found in the Late Archaic and Early Woodland period cultures occupying the Great Lakes and upper Midwest in the millennia preceding the Middle Woodland period. In the Late Archaic period, approximately 5000–3000 years ago, the ideology that focused cultural energy on mortuary ritual ceremonialism emerged in these regions. Important

individuals were buried in prominent locations with rich symbolism. Symbolism was present in artifacts interred with the burials, but also in the construction of the burial tombs and the methods of treatment of the dead. Rubbing corpses with red ochre was practiced by some of these cultures. Burial locations were chosen that included visible natural knobs or prominences, shell middens, and sometimes glacial kames. Names given to identify some of these cultural complexes include Old Copper, Red Ochre, Glacial Kame, Orient, and Meadowood. Very little definitive knowledge exists concerning the broader questions of settlement and social organization for most of these peoples, although evidence seems to point to most of them being seasonally mobile hunters and gatherers, some of whom began to experiment with the plants that later became the EAC crop system.

The presence of ceramic technology in Eastern Woodlands cultures about 3000 years ago has been used to create one of the period boundaries between the Archaic and Woodland periods. During the Early Woodland period, approximately 3000 to 2200 years ago, the first burial mounds were erected in the middle Ohio Valley. Meadowood people, in Ohio and upstate New York, may have been among the first people to erect small earthen mounds for the dead. Some of the people who erected these mounds were the direct ancestors of the Ohio Hopewell. One of the clear purposes behind building the mounds, besides the obvious function of providing a final resting place for the dead, was the social separation of ritual and domestic space. What the Hopewell later accomplished with the separation of space by their earthwork and mound centers is a logical conclusion to this practice.

In the middle Ohio Valley, beginning about 2500 years ago, a distinctive burial ceremonial complex had emerged that focused on the building of dispersed conical mounds. This complex is today known by the term Adena. It, too, was named at the turn of the 20th century, based on the excavation of a 26-foot-tall conical mound by Ohio Historical Society archaeologist William C. Mills on the Adena Estate of Governor Thomas Worthington in Chillicothe, Ohio, less than a mile from the Hopewell Culture National Monument at Mound City. The Adena are also known to have constructed small geometric circles, sometimes encircling mounds and sometimes not. The Adena are logically the clear ancestors of Hopewell, at least in places like the Chillicothe and Licking regions of central

Ohio. However, the Adena did not evolve into Hopewell throughout their range, creating a complex dual-tradition phenomenon that has vexed archaeologists who prefer simple ancestor-descendant relationships between cultural traditions. In peripheral locations, like the Muskingum River Valley and the Hocking River Valleys of southeastern Ohio, the Bluegrass Region of northern Kentucky, the White River Valley of eastern Indiana, and the Kanawha River Valley of West Virginia, Adena communities appear to have existed until as late as A.D. 200–300, living alongside contemporary Hopewell communities located in the Scioto, Licking, and Miami Valleys in south central Ohio.

Symbolism

Hopewell symbolism is generated in several different mediums and scales. The exact meaning of these symbols is, of course, shrouded in mystery, but there is scholarly consensus about the self-evident iconography in some mediums, like the effigy pipes. A dominant Hopewell motif is the raptorial bird. This motif occurs in the form of stylized eagles, hawks, or falcons on ceramic vessels, on copper plaques (cold hammered from nuggets collected near Lake Superior), on shells collected on the Gulf Coast, on pipes carved from Ohio pipestone, and on carved mica sheets (collected in western North Carolina). Other animals, like waterfowl, deer, and bear, are also common motifs in Ohio Hopewell art. Human forms are more rarely depicted, but human hands cut out of mica and copper are known, and a series of ceramic figurines were recovered from mound contexts, which provide insight into clothing and hair styles (men may have used the “Mohawk” hair style).

Next to the zoomorphic forms, there were an abundant number of geometric forms represented in Ohio Hopewell symbolism. The overriding principle seems to be symmetry. Circles, commas, and squares are common; examples of swastikas have been recovered as well. Geometric forms are expressed in the earthworks. In the case of the large squares, circles, and the two known octagons, a convincing case can be made for elaborate astronomical alignments. The solstices are marked, but so, too, are still stands of the moon. Alignments to bright stars and constellations are less well marked by Hopewellian astronomy but do appear to have been important in some cases.

The underlying symbolism in Hopewellian art, burial customs, and earthen architecture has been

interpreted in a variety of ways. Some view the earthworks as a symbolic great house capable of bringing together all the members of a community within one socially circumscribed place. The symbolism expressed by artifacts, on the other hand, seems to have functioned at various societal scales, conveying social status and marking social boundaries. Individuals displayed artifacts that sent messages to observers; some of these messages could only be understood locally, while others were more universally understood across regions. The mortuary rituals may be interpreted as marking cults of world renewal. These cults served to incorporate individuals from divergent age-sets, but also from neighboring communities, into inclusive social identities, which dampened conflict and promoted within- and between-group cooperation.

Finally, some of the symbolism is clearly representative of magical or shamanistic practices. In some cases, such as the way obsidian is used, there is an implication of cross-country treks to the very edge of the known world; the obsidian in Ohio Hopewell mounds and earthworks was obtained from the Yellowstone region in the western United States, a distance of upwards of 1800 miles from the Ohio Hopewell centers. Some unique burials may be interpreted as representing shamans, and if so, include the ritual tools or paraphernalia that Hopewell shamans used in their craft.

Settlement, Social Organization, and Subsistence

When the great Hopewell earthwork and mound centers were first observed by Euro-American settlers, the assumption was that only a complex society with a centrally organized political system, itself supported by full-time intensive agriculturalists, could have carried out such a cultural achievement. In fact, scholars like Squier and Davis linked Hopewell, via the trait of mound/pyramid building, to the classic Mesoamerican civilizations in order to provide the level of complexity they perceived to be necessary to account for the archaeological record. Few agreed with Squier and Davis, although some sort of Mesoamerican connection based on symbolism continued to be discussed well into the mid-20th century.

Similarly, it was also widely popular during the 19th century to explain the Hopewell earthworks as the product of some mysterious lost civilization.

Some, like the emerging Church of Jesus Christ of Latter-day Saints (the Mormons), saw this civilization as evidence for the presence of the Lost Tribes of Israel in North America; others saw the mounds as evidence of a Phoenician presence or even a Viking presence linked to the classic Greenland sagas relating the travels of Leif Eriksson and his kin. These explanations are now collected together under the rubric of the “Myth of the Moundbuilders.” In all of the various versions of this myth, the explicit assumption at the center is that Native Americans, as typified by the “savage” tribes encountered by Europeans upon contact with the New World, could not possibly have built the earthworks and mounds. This perspective is clearly an extension of the prevailing view of progressive cultural evolution that dominated 19th-century thought. Native Americans were placed so low on the cultural development ladder that supporters of the myth could not perceive how they could accomplish works of such civilized complexity.

The height of absurdity was reached when, in order to strengthen their claim, adherents to the Moundbuilders myth began planting fraudulent tablets and other similar evidence in the mounds for excavators to recover. Some of these, like the Newark Holy Stones from Licking County, Ohio and the Davenport Tablet from Iowa, took generations to expose as frauds, while others, like the Bat Creek Tablet from Tennessee, still have supporters who believe in their authenticity. Ultimately, the foundations of the myth unraveled

from the ground up as a result of the extensive mound explorations sponsored by the Bureau of American Ethnology, which were led by archaeologist Cyrus Thomas. He clearly identified ancient Native Americans as the moundbuilders in his classic 1890–1891 *Report on the Mound Explorations of the Bureau of American Ethnology*, debunking the “Myth of the Moundbuilders” and setting the stage for a productive period in Hopewell archaeology that eventually led archaeologists to focus on habitation sites, subsistence

patterns, and community organization, rather than myopically continuing the efforts that focused on digging up the Hopewell mounds.

One aspect of the Moundbuilders myth that did not fade with Thomas’s research was the assumption that Hopewell populations relied on some form of intensive agriculture. No one could envision how ancient Americans could have built the mounds and earthworks without a reliable food source. Most assumed that this crop system would be based on the same system of food production seen across the Americas: the “three sisters” of corn (maize, *Zea mays*), beans (*Phaseolus vulgaris*), and squash (*Cucurbita pepo*). When Europeans first arrived, the three sisters were prevalent among the Northeastern Iroquoians and Algonquians, the Southeastern “five civilized tribes,” the Southwestern Puebloans, and throughout Mesoamerica and South America. Yet, even by the mid-20th century there was no concrete evidence supporting this assumption for Ohio Hopewell. Then, in the first major excavation at an Ohio Hopewell habitation, a couple of carbonized corn cobs were recovered in a sealed midden context that seemed to solidify the case for Hopewellian maize agriculture. This excavation was conducted in Ross County by Olaf Prufer in 1963, at a site he called the McGraw site. While the legitimacy of these cobs has been debated, at this time they do seem to represent real examples of Ohio Hopewell corn. However, what has failed to materialize is widespread evidence of an intensive maize agriculture

lifestyle that supported the mound- and earthwork-building activities of the Hopewell people.

Instead, abundant evidence has been collected suggesting that the Ohio Hopewell populations were food producers, but that they cultivated an extensive array of indigenous starchy and oily seeds instead of the three sisters. These crops have come to be known as the Eastern Agricultural Complex (EAC), and except for widespread use of squash (especially the bottle gourd (*Lagenaria* sp.), but also relatives of the pumpkin and summer squashes, (*Cucurbita pepo* sp.)) and an occasional ear of corn, the EAC is composed of locally derived woodland species. Individual aspects of the complex appear to have evolved as domesticates in the Eastern Woodlands beginning between 3500–4500 BP, but did not take form as a fully integrated food producing system until the Early-Middle Woodland periods, approximately 2500–2000 years ago. The list of starchy seed plants includes Goosefoot (a type of chenopod, *Chenopodium berlandieri*), Maygrass (*Phalaris caroliniana*), Erect Knotweed (*Polygonum erectum*), and Little Barley (*Hordeum pusillum*), while the oily seed list includes only two plants, Sunflower (*Helianthus anuum*) and Marsh Elder (*Iva annua*).

Smithsonian archaeologist Bruce Smith refers to the EAC complex as a form of low-level food production, which probably contributed no more than 20–40% of the calories the Hopewell populations needed to sustain themselves. He believes that the EAC complex contributed a reliable and predictable food source for Hopewell populations, but at caloric levels far below those contributed by intensive agricultural systems based on maize, beans, and squash (or the wheat, barley, and lentils crop system of the Fertile Crescent). Rotating small garden patches, most likely relying on a slash-and-burn method for forest clearance, is the consensus view of how these crops were cultivated. No evidence, or need, seems to have existed for water supplementation such as irrigation canals. Wood charcoal evidence recovered from Hopewell earth ovens and storage pits indicates that the EAC crop system began to produce the first significant cultural effects on the mature Eastern Woodlands deciduous forest—effects that were considerably magnified by populations utilizing the same crop system, but much more extensively, during the following Late Woodland period, beginning after A.D. 400. It should also be noted that it was not until after about A.D. 900 that intensive agriculture centered on the three sisters took a serious foothold in Eastern Woodlands populations.

The relatively low caloric input from the EAC crops required Hopewell populations to maintain an active practice of collecting natural, seasonally occurring plants and animals; by necessity they continued to practice the hunting-gathering techniques evolved in innumerable local environments by their Archaic ancestors. Whether or not the Ohio Hopewell populations were tethered to the land by their crop system, and could therefore be considered a sedentary population as opposed to a seasonally mobile population, is a current point of major contention in the Hopewell literature. It is clear, though, that the limitations on sources of reliable protein created by the lack of domesticated animals in the Eastern Woodlands, as elsewhere throughout the Americas, put a premium on the hunting of large wild animal species during the Middle Woodland period. Of these wild animals, the white-tailed deer (*Oedocoileus virginiana*) is by far the most important game species, typically comprising over 75% of faunal remains recovered from Eastern Woodlands sites, Ohio Hopewell sites included. After deer, almost every conceivable mammal, fish, and bird species that could be hunted or collected was utilized. Turkey, elk, bear, rabbit, raccoon, and a variety of waterfowl, fish, and shellfish appear frequently in the faunal record alongside deer. On the plant side, emphasis appears to have been placed on collecting a variety of nuts, including hickories, walnuts, hazelnuts, and acorns. Likewise greens, tubers, and berries were also collected when seasonally available. The unique system of Hopewell land management has led some archaeologists to argue for a distinct Hopewell niche. They argue that the gardening system produced a synergistic effect on the landscape that increased the carrying capacity of local environments by creating artificial breaks in the mature climax deciduous forest. Abandoned garden patches promote the growth of forest edge plants such as berries and hazelnuts, which attract animals such as deer and raccoons. The higher local carrying capacity, combined with the EAC food production, may have provided these populations with the necessary resources to limit their seasonal mobility.

Even though evidence for this component of Ohio Hopewell culture is now relatively abundant, there remains a great deal of controversy surrounding the interpretation of settlement, social organization, and subsistence patterns. An index fossil artifact type that characterizes Ohio Hopewell sites is the small delicate blades, called bladelets, produced from prepared cores

of the highest quality cherts and flints, like those found on Flint Ridge in Licking County, or the Harrison County cherts of southern Indiana. Evidence indicates that Ohio Hopewell populations were dispersed across the landscape in small family or extended family groups, rather than aggregating together in towns centering on the earthworks. Over 150 years of excavations at earthwork and mound centers failed to produce much evidence of permanent habitation at these sites. Consequently, it was Prufer who began to look for evidence of Hopewell habitations in the river valleys away from the great centers. His McGraw excavation, though admittedly limited to the midden deposit, formed the cornerstone for his central thesis that came to be known as the Vacant Center model. Prufer's interpretative framework for Ohio Hopewell settlement patterns included the following key elements: (1) the general settlement pattern is based on territorially defined, vacant ceremonial centers, supported by dispersed dependent villages; (2) these dispersed habitation sites were small, consisting of no more than one to a few families, so he referred to them as hamlets or farmsteads; (3) the dispersed habitation sites were semi-permanent, meaning they shifted their households and gardens frequently, although specific locations were inhabited year round; (4) the dispersed habitation sites practiced some level of food production; and (5) these dispersed groups periodically congregated at the earthworks to conduct rituals, like the mound burials, which also served to socially integrate Hopewell communities and provide the interaction context for creating mating networks and other kinds of social bonds.

Additional research, especially in the Licking River Valley, 60 miles northeast of the Chillicothe region, has produced additional support for Prufer's model. This research, conducted by William S. Dancey and Paul J. Pacheco, has produced a refinement and revision of Prufer's model into what they call the Dispersed Sedentary Community–Vacant Ceremonial Center model of Ohio Hopewell community organization. However, some archaeologists argue that the available evidence can also be interpreted as supporting a view of Ohio Hopewell communities that moved seasonally as the resources they were dependent upon became available. Yet, all archaeologists are in general agreement that the Hopewell populations were neither dense nor plentiful in number. Thus, it is assumed that they represent a tribal society, most likely organized along the lines of segmentary

lineages. The conundrum of building massive earthworks and mounds, even if they were built slowly over time, all the while relying on potential natural resource fluctuations, remains a central mystery for those attempting to understand Ohio Hopewell.

Demise

The demise of Ohio Hopewell from the archaeological record has long been considered a classic example of cultural collapse. Internal conflict, invasion by outsiders, climate change in the direction of cooler temperatures, population pressures, adaptive transformation, and even simple cultural fatigue have all been offered as explanations for the demise of the Hopewell. Yet, none of these explanations is fully accepted or supported by available evidence.

Some archaeologists see these changes occurring in what were formerly Adena groups, peripheral to Hopewell, as perhaps central to an explanation for the Hopewellian demise. Throughout the middle Ohio Valley, beginning as early as A.D. 300, a new kind of cultural arrangement in the form of aggregated villages was spreading, ultimately at the expense of Hopewellian communities. These village communities continued to cultivate EAC crops but did so more extensively, utilizing the greater manpower available in village arrangements to make larger garden patches, and presumably extracting a greater caloric return from the crop system. The necessity for hunting and gathering was, of course, never eliminated in these populations, even when they began to farm the three sisters, because of the lack of domesticated animals to provide a reliable source of protein. In this scenario, Hopewell populations are simply replaced, or out-competed by the new social arrangement. It is also true, however, that the social integrative function of Hopewell earthworks and mound centers is replaced in nucleated villages by the day-to-day, face-to-face interaction of the community. Whatever explanation is finally accepted for the end of Hopewell, it is clear that after about 600 years of stability, by approximately A.D. 400, the earthworks and mounds we attribute to Ohio Hopewell were no longer being built in the Ohio core area.

The Amerindians known as the Ojibwa, Ojibway, Ojibwe, Chippewa, Bungi, Mississauga, Saulteaux, or Anishinaabe (as they call themselves) number well over 220,000. Their territory extends east to west from Lake Ontario to Lake Winnipeg and north to south from the Severn River Basin to Minnesota, Wisconsin, and Michigan. In Canada there are over 100 Ojibwa First Nation bands located in the provinces of Ontario, Manitoba, Saskatchewan, and Alberta. In the United States there are 22 federally recognized Ojibwa bands: the Turtle Mountain, Sault Ste. Marie, Red Lake, Minnesota, Lac Courte Oreilles, White Earth, Bad River, Leech Lake, and many others in Michigan, Wisconsin, Minnesota, North Dakota, and Montana. Historically the Ojibwa were never a single tribe in the political sense but rather consisted of a number of bands sharing a language and culture. They are grouped by scholars into four subtribes: the Southeastern, Southwestern, Northern (or Saulteaux), and Plains (or Bungi) Ojibwe.

There is disagreement concerning pre-contact origins and cultural development: while most Ojibwa maintain that they, like all other Native Americans, are autochthonic, many scholars insist that the ancestors of the Ojibwa originated in Northern Asia and moved across the Bering Strait to the Atlantic Ocean. Then, following an epidemic in 1400 C.E., they retraced their steps, going as far as the western shores of Lake Superior. The Ojibwa heartland today is located in

the vicinity of Sault Ste. Marie, Michigan, but this was not always the case. The ancient migration legend, recorded on birchbark scrolls, recounts a long journey from the lower St. Lawrence River up past present-day Montreal, continuing northwest behind Manitoulin Island to St. Mary's River. During the 17th and 18th centuries, they moved into Michigan, Wisconsin, Minnesota, Western Ontario, and Manitoba, with later migrations onto the northern Great Plains in North Dakota, Montana, and Saskatchewan.

The Ojibwa share in both a Woodlands cultural heritage with the Ottawa, Pottawatomie, and Menominee and in a Plains cultural heritage with the Dakota and Lakota Sioux as well as the Cree. Thus, Ojibwa ethnic identity includes a combination of traits from these two distinct traditions. They practice Plains shamanic vision quests and healing rituals, a Rain Dance that is similar to Plains Sun Dances, a Cree-based Smoking Lodge Ceremony, horse breeding and racing. While they share in a Woodlands subsistence pattern that emphasizes fish, wild rice, and maple sugar, they also hunt deer and plant corn and squash. Ojibwa elders smoke and make ritual offerings of *kin-nikinnick*, a tobacco mixture of dried leaves and bark.

Ojibwa society is patrilineal with six major clans—Crane, Catfish, Bear, Marten, Wolf, and Loon—along with several minor ones including Pike, Eagle, Goose, Cormorant, Moose, and Reindeer. Each of these clans is exogamous; thus when a male member of the Loon clan marries a woman of a different clan, their children all belong to the Loon clan. Upon death, the clan animal is drawn, upside down, on the grave marker of everyone given a traditional non-Christian burial. Membership in the Midewiwin, or Great Medicine Lodge, involved many years of vision quests and instruction in herbal healing. The Midewiwin is described by its members as a “gift” carried by the Bear and Otter spirits, or *manitook*, and a megas shell. This shell, which is the main symbol for the society, first appeared in the Atlantic Ocean and then moved westward, disappearing and reappearing again and again until it reached Lake Superior. Members of the society institutionalized shamanism as a philosophy and a religion. The Mide philosophy, which is taught to all initiates, stresses the importance of maintaining balance in one's life and showing respect for all other life forms.

Among the Ojibwa there is an extremely close relationship between personal and mythic experience, with myths serving as primary resources for cosmology and worldview. Their life-world is traditionally

described and experienced through key religious symbols, beliefs, and practices as alive with the presence of manitook. These beings inhabit trees, rocks, streams, winds, thunder, lightning, animals, and the sun and moon. Manitook are perceived as other-than-human persons. Spiritual experiences of shamans and dreamers give birth to mythic narratives, and these narratives inform their experiences. Through dreams and vision quests, the Ojibwa elicit revelations that they commemorate in story and perform in ritual. They also gain reverence for the mystery of life that animates all things: humans, animals, plants, and the earth.

Dreams and visions play a central role in Ojibwa culture. Gifted dreamers become respected artists and elders, and children are encouraged to remember and tell their dreams. Since a newborn baby is born “empty” of personality, pressure is exerted upon children to get them to learn about the spiritual world in order “to fill their emptiness.” This is accomplished by learning traditional stories and developing a loving relationship with dream images. In this way, children become proficient at a special state of awareness halfway between waking and sleeping consciousness. During such dreaming, people experience a form of “doubling” or conscious awareness of both being in a dream state and of being sound asleep. Such dream

experiences involve self-awareness, or self-reflection, while otherwise asleep.

Today, while many Ojibwa engage in traditional craft production as well as occupations such as fishing, hunting, and harvesting of wild rice, many others teach in community colleges and universities, or run manufacturing companies, banks, marinas, fisheries, and ferry services, as well as hotels and casinos. U.S. reservations and Canadian reserves are using their casino revenues to establish community infrastructures. Thus, the northern Minnesota Mille Lacs Band used the profits from their casinos to build streets, schools, a tribal

complex, and a museum on their reservation. Today they have nearly full employment together with numerous job opportunities for non-Indians. This has resulted in steadily growing political influence in nearby non-Indian towns. Other Ojibwa bands, however, have not profited from casinos, and unemployment, together with all of the accompanying social ills, is seriously damaging these groups.

OLDOWAN CULTURE

The Oldowan is the earliest of the Lower Paleolithic or Early Stone Age typological “cultures.” At present, the earliest Oldowan sites date from about 2.6 my and come from Gona, in the Afar region of Ethiopia. The Oldowan industry terminates at about 1.6 my, which coincides with the beginning of the Acheulean. The Developed Oldowan, which is concurrent with the Acheulean industry but lacks the characteristic bifaces, continues for several hundred thousand years after the end of Oldowan. However, numerous researchers do not consider the Developed Oldowan separate from the Acheulean industry. In the strictest sense, the Oldowan culture is restricted to Africa, although stone tool assemblages predating the Acheulean have been found in other parts of the Old World recently.

The Oldowan culture is named for the type-site of Olduvai Gorge in Tanzania. Olduvai was first investigated by Heinrich Reck during the early 1910s, establishing the basic stratigraphic framework for future investigations. However, it was Louis Leakey who first recognized the significance of the archaeological remains at Olduvai, and established the Oldowan as a stone tool cultural sequence. Leakey established the Oldowan as a new typological culture. Leakey also established the extreme age of the Oldowan culture at Olduvai during the 1950s, when radiometric dating techniques became available. The realization of the extreme age of the Oldowan had a dramatic impact on the study of hominid evolution during this time period.

The Oldowan is frequently defined as a “chopper” or “chopping tool” industry, and it is usually thought of as made on either rolled stone cobbles or nodules of stone. These notions stem from the prominence of pebble choppers, which occur in high frequencies at many Oldowan sites. These choppers are made by removing a few large flakes from one edge of a cobble. In addition, the Oldowan is defined by the presence of a few other core types: discoids, polyhedrons, spheroids, and simple bifaces. These other core tools are made in a very similar process to the chopper, with flaking simply extended around the perimeter of the core in varying degrees. These core tool types are also accompanied by vast assemblages of unmodified flakes, or *debitage*. The Oldowan also has low frequencies of modified flakes, such as simple scrapers and

denticulates. The Oldowan is also frequently defined by the presence of battered stones, perhaps used for smashing objects or used in reducing stone cores.

Many archaeologists have viewed the Oldowan as a primitive version of the later Acheulean. In this respect, many have seen the pebble choppers as a more basic version of the Acheulean hand axe. In addition, many have noted that the Oldowan and Acheulean are extremely similar and are differentiated mainly on the basis of presence or absence of hand axes. This problem was further complicated by the discovery of many sites concurrent with the Acheulean that lacked hand axes. Such sites were often attributed to the Developed Oldowan. In more recent research, such perspectives have been considered increasingly problematic because of the decreased significance given to hand axes as type specimens of the Acheulean.

In this respect, the descriptions above may be somewhat misleading in terms of the variability present within the Oldowan culture. A seminal study by Nicolas Toth showed that unmodified flakes are actually much sharper than the core tools, such as the characteristic choppers. This pointed to the possibility that the focus on core tools was misplaced, and that the real desired end product was sharp flakes, which had been seen as waste up to that time. Toth suggested that core tools were, in fact, the result of particular strategies of core reduction aimed at producing usable flakes, and were thus not intentionally designed. In this way, the morphology of cores, which was the typological basis on which the Oldowan had been defined, was really the accidental result of strategies for the removal of sharp flakes. This presented a substantial critique of Oldowan stone tool typology, which was based entirely on core tools. For this reason, current research tends to give less significance to such typological labels, and focuses more on the inference of behavior linked with a more specific absolute chronology.

Most early researchers of the Oldowan culture felt that its makers were primarily hunters of large game and that this was the evolutionary force that caused both the development of large brains and cognitive complexity and the development of stone tool technology. Evidence of this was initially perceived in the large assemblages of faunal remains that accompany many Oldowan assemblages, such as Olduvai. Later investigations, such as those of Lewis Binford, criticized this notion, instead pointing out the role of carnivores in the accumulations of such faunal

assemblages. Despite this, the view remains pervasive that the lithics of the Oldowan culture were primarily butchery implements.

There are numerous species of hominid present in Africa during the span of the Oldowan, significantly complicating the question of who the makers of this industry were. These hominids include the later australopithecines, *Homo habilis*, and *Homo ergaster*. When Leakey discovered the first specimen of *Homo habilis* at Olduvai, he suggested immediately that this hominid, with a larger brain relative to its known ancestors and contemporaries, was the first maker of stone tools. Indeed, this remains the most commonly held opinion on the subject. However, it is also possible that the late australopithecines or even early *Homo ergaster* individuals were the first to make the Oldowan industry. It is extremely unlikely that there will be any unequivocal evidence concerning this question.

Indeed, “Olmec” refers to two things: (1) an art style and symbolic system widely dispersed throughout Mesoamerica; and (2) a pre-Columbian culture that flourished from 1200 to 600 B.C. along the Gulf Coast of Mexico, specifically in southern Veracruz and western Tabasco. Both of these definitions acknowledge the culture’s impact on the pre-Columbian Mesoamerican world; however, debate persists concerning the nature and development of this impact.

Occupation of the Gulf Coast’s lowlands, which comprised the Olmec heartland, occurred as early as 2200 B.C. After 1200 B.C., identifiable characteristics of Olmec culture crystallized. Members of the culture may have collectively spoken an early version of the Mixe-Zoque language. Egalitarian farming communities developed into a multi-tiered hierarchical system of settlement, which integrated towns, smaller villages, tiny hamlets, craft workshops, and isolated sacred spaces. Within this system, the archaeological sites of San Lorenzo, Laguna de Los Cerros, La Venta, and Tres Zapotes were four important centers, which were located in distinct eco-zones. Recent archaeological projects involving survey and excavation have documented considerable and long-term occupation within these centers’ cores, as well as in their adjacent hinterlands. This finding has effectively debunked the long-held belief that these sites functioned as vacant ceremonial centers.

San Lorenzo, the earliest of the known Olmec centers, was established around 1200 B.C. The center is located atop a low hill looking out over the Río Chiquito, an arm of the Río Coatzacoalcas. Most likely, this location facilitated movement of ideas, goods, and people. Between 1150 and 900 B.C., the center’s inhabitants leveled San Lorenzo’s hilltop and erected earthen terraces, an endeavor requiring considerable human labor. By 900 B.C., San Lorenzo’s population had declined, and for reasons not yet understood, the center was eventually abandoned. Following San Lorenzo’s decline, the sites of La Venta and Laguna de Los Cerros rose in prominence. Ongoing research at Laguna de Los Cerros has shed light upon the site’s history and recognized its prime geographic location. While investigations at Laguna de Los Cerros have been recently initiated, La Venta has long been a focus of researchers’ interests and is the most intensively investigated of the Olmec sites. Frans Blom and Oliver La Farge first documented the site in 1926, incorrectly identifying it as Maya. Subsequent research at La Venta drew attention to the

The term “Olmec” derives from Olmeca-Xicalanca, the Aztec name for conquest-era Gulf Coast traders. This designation, however, is not without problems given the ethnic and historical links it implies.

Olmecs' substantial population levels, complex sociopolitical organization, and far-reaching trade networks. The site is located atop a salt dome and surrounded by marshes. In keeping with placement of lowland sites near rivers, La Venta overlooked the Río Palma, which has since run dry. The center's most distinguishing architectural feature is the Great Pyramid, an artificial "mountain" approximately 100 feet high. Despite heat, humidity, and periodic flooding, the center's apogee extended for three centuries. By 400 B.C., the site was abandoned. Tres

Zapotes emerged as an important center following La Venta's demise. Despite being distinguished as the first archaeologically investigated Olmec center, Tres Zapotes is less remarkable in size and sociopolitical stature. In 1939, Matthew and Marion Stirling commenced the long history of research conducted at the site. In more recent work, David Grove has highlighted the upland environment in which Tres Zapotes is situated, arguing that its proximity to specific, local resources like basalt would have facilitated commercial relationships with lowland centers to the east. The same hypothesis can be extended to Laguna de Los Cerros, which was also located on the western edge of the Olmec heartland. Recent work has found that occupation of Tres Zapotes extended into the Classic period (ca. 300 B.C.–A.D. 300), debunking the idea of an Olmec "collapse." In this period, the inhabitants of Tres Zapotes retained elements of Olmec culture but also incorporated influences from elsewhere in Mesoamerica.

In common, all of these Olmec centers possessed architectural features requiring considerable construction effort, such as monumental earthen platforms and ridges, ball courts, artificial reservoirs, and drainage systems carved from stone. These centers were also characterized by conspicuous consumption, as excavators have uncovered rich offerings of luxury goods intentionally cached beneath buildings. At La Venta,

for instance, four large mosaic masks of serpentine blocks situated in colored sands were uncovered beneath the site's Complex A. Furthermore, it is argued that the arrangement of buildings at sites conveys cosmological beliefs, while buildings' forms replicated landscape features regarded as sacred.

In addition to major centers, Olmec sites included isolated sacred spaces used expressly for repeated and long-term ritual purposes; these sites have no evidence of domestic occupation. Proximity to bodies of water, mountains, and caves—natural features deemed cosmologically important—perhaps provided the impetus for their characterization as sacred. El Manatí represents one of these sacred sites. Located 20 km from San Lorenzo, the site, which served as a place for ritual offerings from 1600 to 1000 B.C., is associated with a natural spring and hill. Fortunately for archaeologists, the inorganic bog soil into which offerings were deposited preserved them for millennia. Offerings included remarkably well-preserved wood busts of adult males and females, jade axes, rubber balls, copal, dismembered human remains of children, and faunal remains. Idiosyncratic and realistic features, suggesting individual portraiture, characterize wood busts.

The nature of political organization and social integration of Olmec centers remains a point of scholarly contention. General consensus advocates

the notion of a theocratic chiefdom. Such a sociopolitical system involves governance of each center by a single, elite individual, or chief, who exercises authority over all things religious and monetary. With respect to the former, artistic representations' iconographic symbols and motifs suggest that the Olmecs practiced a religion distinguished by shamanism. Shamans, or shamanic chiefs, mediated between the natural, earthly realm and the supernatural realm of the ancestors and deities. As first pointed out by Peter Furst in 1968, Olmec sculpture also depicts shamans' supernatural power and ability to transform from human to animal spirits. Use of psychotropic drugs may have facilitated shamanic transformations. Aside from religious activities, the chief's monetary responsibilities were related to food production and collection of tribute. An elite minority, presumably related to the chief, would have also exercised economic control over food tribute and trade networks. Trade with Mesoamerican groups distant from the Olmec is evidenced by materials such as blue-green jade from the Motagua Valley in Guatemala, fine white kaolin clay from Chalcatzingo, magnetite from the Valley of Oaxaca, and obsidian from central Mexico and the Maya highlands. Interactions via trade would have afforded the opportunity for communication of religious, social, and political ideas as well.

Much of this dialogue between the Olmecs and their distant Mesoamerican neighbors is supported by the appearance of Olmec art, or local expressions with characteristic features, in widely dispersed locales. Olmec art possesses distinctive stylistic traits that first appeared in the Olmec heartland between 1250–1150 B.C. Rulership and shamanism are the dominant themes. Most notable for their size and early dates are the three-dimensional human figures carved from stone. These include colossal basalt stone heads, seated and kneeling individuals, throne-like altars, and stelae. The effort that would have been required to procure enormous basalt boulders from their source, the Tuxtlas Mountains, cannot be overstated. First reported in 1862 at the site of Hueyapan in Veracruz, colossal stone heads were in fact investigators' earliest exposure to Olmec culture. Scholars have convincingly argued that carved heads portray individual Olmec leaders. Often these monuments were found defaced or intentionally broken, which possibly signified the cessation of a leader's rule or life. Olmec-style art is also found on a considerably smaller scale, as exemplified by portable artifacts.

Ceramics include incised pottery vessels, hollow baby-faced figurines, solid female figurines, and zoomorphic vessels. Jade, a notoriously difficult stone to work with, skillfully carved into figurines, plaques, pendants, and axes were also included in the repertoire of Olmec artisanship.

The appearance of Olmec artistic styles throughout Mesoamerica gave credence to Miguel Covarrubias's argument that the Olmec represented a pervasive "mother culture" from which all other Mesoamerican civilizations sprang. Advocates of this model argued that Olmec culture was unequaled with respect to sociopolitical complexity, religious influence, and economic reach. Subsequent excavations at sites in the Olmec heartland have uncovered numerous artifacts with typical attributes, adding further support for the dispersal of these artistic symbols and their encoded beliefs from the center outward. Since Covarrubias's pronouncement in the 1940s, scholars have heatedly debated the notion of the Olmec culture as Mesoamerica's first civilization.

The counterargument to the "mother culture" model has been deemed the "sister culture" model. Scholars who argue against Olmec-centric models do not emphasize diffusion but consider the developmental processes and interactions of multiple societies. The notion of a central political authority concentrated in the Olmec heartland is disputed, and Olmec-style art is explained as the product of interaction by artisans from different Mesoamerican cultures. Proponents of this model also suggest that the Olmec were no more advanced than other contemporaneous Formative cultures, such as those found at Chalcatzingo in Morelos, the Valley of Mexico, and the Valley of Oaxaca. Sociopolitical development in these areas appears to be concurrent and not influenced by the Olmec. For instance, archaeologists working in the Valley of Oaxaca have identified hierarchically organized chiefly centers, craft workshops, buildings constructed with lime plaster and stone masonry and solar or astral orientations, and trade networks of prestigious goods. Distinct from Olmec imagery of rulers linked to powerful forces in the cosmos, Oaxacan authority is depicted by slain captives and territorial triumphs. Kent Flannery and Joyce Marcus, proponents of this model, argue for the Olmec as a paramount chiefdom, a large chiefdom that combines sacred authority and secular power, that rose, peaked, and eventually collapsed in a landscape of traditional or open chiefdoms. Chiefly

centers throughout Mesoamerica were concentrating power, intensifying agriculture, and exchanging sumptuary goods and ideas.

Drawing on both of these opposing models, Kent Reilly, III has suggested a happy compromise that does not de-emphasize the Olmecs' importance but situates the culture within a larger Mesoamerican landscape. He recognizes that the Olmecs were a significant cultural force whose influence continued after their decline, but he also acknowledges interaction with other Mesoamerican cultures. Art styles and associated symbols did originate with the Olmecs, but the culture did not represent a centrally organized society. Rather, sharing of ideas, beliefs, and practices occurred throughout Mesoamerica, resulting in a localized variation on a theme. Continued research efforts in the Olmec heartland and throughout Mesoamerica will further clarify our understanding of this long-debated issue.

OMAHA INDIANS

The Omaha (also called Maha) are a Native American nation with a reservation in the northeastern corner of Nebraska, tribal headquarters in Macy, and a government-to-government relationship with the United States that was documented by the treaty of

March 16, 1854. This treaty ratified reservation boundaries and recognized the Omaha as a sovereign nation governed by a constitution and elected tribal council.

Today, the Omaha farm private reservation holdings (allotments) and collectively operate a casino and resort. They have also entered the professional workforce, becoming attorneys, doctors, accountants, and administrative executives. For example, Susan La Flesche Picotte (1865–1915) was the first Native American woman physician. The Omaha also cooperatively own the Reservation Health Center, which provides food to the elderly and a youth program, among other services.

The Omaha speak English, though new activism encourages young people to study Omaha-Ponca (the Cegiha, Dhegia, branch of the Siouan language family). During the colonial period, forced removal of Omaha children to residential Protestant mission schools where they were forbidden to speak their language caused many to cease speaking Omaha-Ponca. Fortunately, due to the diligence of many anthropologists and linguists, there exist dictionaries, grammars, and Omaha-Ponca texts.

The Omaha intellectual Francis La Flesche (1857–1932) initiated both the Reverend James Owen Dorsey (missionary, linguist, and ethnographer for the Smithsonian Institution's Bureau of Ethnology) and Alice Cunningham Fletcher (ethnographic researcher for Harvard's Peabody Museum) into Omaha language and culture, which resulted in classic studies. Francis La Flesche also wrote a text of Omaha tales at the behest of Franz Boas that was never published, though La Flesche published other works. An ethnographer himself, La Flesche's obituary appeared in the *American Anthropologist*. There are many excellent studies that focus on Omaha folklore and literature as well as biographical accounts of prominent Omaha.

Because Omaha-Ponca was an orally transmitted language, written documentation of the Omaha begins with the journals of French trader Louis Jolliet and French Jesuit Father Jacques Marquette in the latter part of the 17th century. Both men recorded that the Omaha were semi-nomadic hunters, gatherers, and horticulturalists of corn, squash, and beans who lived in earth-lodge villages during the spring and summer months. Women owned the earth-lodge houses, and following marriage a man resided in the household of his mother-in-law. In July, all the clans

hunted the bison together with great ceremony, returning to their villages for the autumn harvest. After the harvest, Omaha villages broke up into small family bands to hunt game in the Upper Missouri Valley, which is the region now designated Iowa, Nebraska, and Minnesota, at which time the Omaha lived in portable, hide-covered *tipis* also traditionally constructed and set up by the women.

Throughout the U.S. colonial period (1776–1900), the government regarded these semi-nomadic subsistence patterns as evidence of the supposed “uncivilized” nature of Native American culture. Because earth-lodge horticultural villages were left unoccupied during the winter months, American authorities defined them as “abandoned.” In fact, Native American tradition did not recognize private ownership of land. The U.S. government used these semi-nomadic subsistence patterns to expropriate the North American continent from the Native Americans. However, prior to the expropriation of Omaha territory by the U. S. government, and in addition to hunting, gathering, and horticultural subsistence activities, by the late 1700s to the early 1800s the Omaha controlled Missouri River trade. Consequently, the Omaha were considered quite wealthy by the standards of the day.

In terms of social organization, the Omaha divided themselves into two moieties (Earth People and Sky People), subdivided further into ten clans. Among the ten clans, seven particular clans were the holders of the Seven Sacred Pipes of Omaha traditional religion. From these seven clans were drawn the Council of Seven Chiefs. The moieties and clans ensured (and continue to do so) a place for every individual within the Omaha nation, connecting the clans by means of social relations and obligations that regulate not only economic pursuits and conflict but also spiritual life.

Traditional Omaha religion is complex and subtle. An elaborate cosmology reflects the system of moieties, clans, and gender relations. The Sky People moiety represents the great cosmic Father Spirit or father principle symbolized by The Sacred Pole, “Umon-hon’ti,” also referred to as the “Venerable Man.” The Earth People moiety represents the great cosmic Mother Spirit. Her emblem is the Sacred White Buffalo Hide, “Tae-thon-ha.” The Omaha refer to Tae-thon-ha as Umon-hon’ti’s “companion.” Both Umon-hon’ti and Tae-thon-ha have a Sacred Pipe to connect the Omaha to these spiritual principles by

means of “fragrant smoke,” which carries prayers to the world of spirit. Many Omaha continue to practice an amalgamation of traditional Omaha religion with various forms of Christianity.

Many excellent anthropological, historic, linguistic, and biographical works focus on the Omaha people.

At the time of the first European contact, among the aboriginal groups that inhabited the archipelago of Tierra del Fuego were the Selk’nam, or Onas. Onas was the name their neighbors, the Yaganes or Yámanas, gave to this group. The Selk’nam lived in the northern steppe grassland of the grand island of Tierra del Fuego. However, they did not have a permanent settlement; they migrated throughout their territory according to seasonal climate changes and in search of a better campsite, food, firewood, and water. Like the Tehuelches of Patagonia’s plateau—to whom, according to some archeological records, Onas are related—they had a pedestrian-hunter economy that made the guanaco their most important resource, not only for alimentation but also for apparel and dwelling.

Guanaco hunting required strategies such as high prey dismembering, high-value anatomical part selection, and long distance transportation. Archeological remains provide accounts of these strategies reflected

in the tools found: projectile points, harpoons, wedges, scrapers, axes, drills, and wooden bows. Some of these tools were made of bone and guanaco tendons or nerves. Guanaco nerves, tendons, and membranes were used as sewing threads and also to tie and braid fishing nets and baskets. Selk'nam also consumed sea lions and other marine mammals beached on the coasts. Their diet was complemented with mushrooms, wild celery, and different kinds of berries, birds, fish, and mussels. An increased consumption of fish and shellfish after European colonization may reflect sea lion diminution caused by sealer activity in the region.

Onas were organized in groups or bands of individuals related to each other. Bands were the basic unit of geographical residence, subsistence, and travel. They did not have a permanent chief except during war periods. However, they did respect the authority of elders and shamans. Each Ona group lived in its own territory or hunting zone and migrated through it in search of food. They had a clear social division of labor: women were in charge of food, water, and wood collection and men of hunting. The violation of hunting delimitations was a sufficient reason for war between groups. Their nomadic life was momentarily interrupted when a sea mammal became stranded. In this case, different groups gathered together at the beach until the animal was consumed. Another situation that made groups stay in the same place longer than usual was when young men were inducted in religious ceremonies called *hain*. The purpose of this induction was twofold. First, it was aimed at maintaining and justifying masculine hegemony. Second, it served as a youth intensive training on hunting, surviving, and instruction on Selk'nam's beliefs about the world. Ethnographers and colonizers alike were impressed by the complexity of the Onas belief system.

By the late 19th century, Onas existence was precarious. Not only had they been engaged in a process of acculturation that altered most aspects of their livelihood, but they had been segregated by European ranchers to the innermost section of the island or in Salesian missions and reservations. The last full-blooded Selk'nam died at the end of the 20th century.

OPARIN, A. I. (1894–1980)

Aleksandr Ivanovich Oparin, a Russian biochemist, advanced theories on the origin of life based on the chemical components of the early atmosphere. At first his theories were met with skepticism, but later they achieved some measure of acceptance in the scientific community.

Oparin was born in the village of Uglich, near Moscow. His family moved to the Russian capital when he was nine, due to there being no secondary school in Uglich. Oparin stayed in Moscow and eventually attended Moscow State University, where he majored in plant physiology. He was greatly influenced by a plant physiologist at the university by the name of K. A. Timiryazev. Timiryazev had known Darwin, and the influence of this relationship can be seen often in Oparin's writings.

Oparin's theory was intended to extend Darwinian evolution back through time to show how simple chemical compounds, both organic and inorganic, could have formed into complex organic compounds, and how the first organism could have formed from these complex organic compounds.

Oparin made his first public presentation of these views in 1922 during the meetings of the Russian Botanical Society. Oparin's theory relied on several ideas that were regarded with skepticism by his peers, for example, the method of nourishment acquisition he proposed for the first organism. Oparin claimed that the primordial organism was heterotrophic; that is, it obtained nutrients by consuming organic compounds. More popular was the theory that the first

organisms would have had to create their own nutrients in a manner similar to that of modern plants.

He also proposed tenets in his theory that contradicted the view of life as essentially molecular and further claimed that living organisms cannot survive without receiving energy and nutrients from their environments. Both views were controversial. Despite opposition, Oparin was able to do much of his work as a result of advancements in organic chemistry, the likes of which were not available to earlier researchers in the field.

In 1935, the Soviet government created a biochemical institute in honor of Oparin's friend and mentor A. N. Bakh. Oparin was instrumental in the founding of the Moscow-based institute and served as its director until his death. While at the institute, Oparin did much to advance the study of the origin of life. In 1957, the first international conference on the origin of life was held under his direction in Moscow, with 16 countries represented. The conference met twice more, once in 1963, and then again in 1970. It was during the 1970 meetings in Pont-à-Mousson that Oparin was named the first president of the new International Society for the Study of the Origin of Life.

Oparin also performed research in the fields of enzymology and industrial biochemistry along with his studies into the origin of life, but he remained focused on the last for the most part. On his 70th birthday, the book *Problems in Evolutionary and Industrial Biochemistry* was published in Oparin's honor, reflecting his important contributions to that field. He received a multitude of awards during his life including the Order of Lenin, Hero of Socialist Labor, and the Mechnikov Gold Medal. Oparin died on April 21, 1980.

ORAL LITERATURE

Oral literature, or oral mediums, are stories that are or have been transmitted in spoken forms, such as a public recitation, rather than through the medium of writing.

Many societies, both pre-literate and literate, have a tradition of oral literature that includes short

folktales, legends, myths, proverbs, and riddles. As well, many have a tradition of longer narrative compositions or epics, like the *Odyssey* and the Mesopotamian Gilgamesh creation myth. These oral compositions were added to over many centuries before they were committed to paper.

When compared to written literature, oral literature's distinctive features include spontaneous outbursts of feelings; deep, traditional roots preserved through memory. Folklore and folktales are part of oral literature; it is literature that is not normally read in an academic setting but is more often told at informal gatherings, such as a wedding or a funeral. Those who practice oral literature or "story telling" are not always educated; rather, they tend to be the working person or the elderly member of a family to whom one may normally not pay attention. Many of these stories or oral histories are traceable to ethnic groups; others incorporate elements of more than one ethnic group.

Some prime examples of this type of oral history, or oral literature, that is still very prevalent can be heard in Central America, specifically in Belize and Guatemala, where there is an ethnic mix of Africans, Mayans, and the dominant ethnic group, the Spanish. The oral literature in Belize and Guatemala is rich in the overlapping of these peoples. The overlaps underline remarkable degrees of concurrence, not only in the folk legends but also the cosmology of Central America, despite ethnic differentiation. It is the appreciation and depth of such cross-fertilization that produces the collective consciousness of these peoples as one people tied together by their oral history and their oral literature.

Oral literature and oral histories are inevitably tied to the concepts of time and memory. At the level of oral literature and oral language, however, permanence depends solely on memory. Implicit in this concept of an oral literature is the recollection of time, not as a defining method of measurement, but in the sense and awareness of duration and also the differences between past, present, and future. B. L. Whorf's study of Hopi oral literature provides powerful evidence of a universal connection between time and language and the advent of oral histories and oral literature.

Oral literature often incorporates elements of the past and the present with some mention of the future; such stories are rich with metaphors and often contain moral and ethical messages. Other times oral

literature is simply a story that involves the recollection of a particular historical event, or a great message of passage, or an odyssey. Oral literature is often a simple trip through the recollected experiences of a storyteller, the sum of his or her life, loves, passions, and the ways in which an individual acts in a given situation. Oral literature is, in many cases, the only knowledge that a people have to understand their heritage and their ancestry, where they came from, where they have been, and where they are going.

The Yucatec Maya of the Belize River Valley are centuries removed from their great historical ancestors; removed by time, but not by memory. The oral literature of the Yucatec is rich with the myths and legends of the ancient Mayans who once ruled the entire Yucatan Peninsula. Their lives are tied to their past, both Mayan and later Spanish Catholicism. Such oral literature is bursting with memories and images of the people, their land, and the spirits of the jungle places. One such folktale is of the Alux, the guardian spirit of the archaeological site and the surrounding land. The Alux is a dominant oral character among the Yucatec Maya and is spoken of mainly in villages such as San Antonio and San Jose Succotz, in the Cayo District. Oral stories of the Alux are also told at Ambergris Caye on the coast of Belize. The Alux is also referred to as Duendecillo, and Donato and his brothers. Although only one foot high, the Alux has the appearance of a robust, arrogant Maya. The Alux is united to the Mayan farming community and the milpa, and is said to take care of the lands and the villages that are near the milpa. The oral story of the Alux is told by the Yucatec medicine people, while they fashion from clay and other fluids the Alux figure. The Alux serves a social function within the village; it is the reminder of the past tied together with the present and the daily struggle to work the land. Each variation on the Alux is the interpretation of the storyteller as he or she weaves the tapestry of life in the Belizean River Valley and the daily interaction with the land.

Oral literature can also be seen as the combination of personal history and the cultural history of an ethnic group, a region, and a smaller social unit: family and community. Thus, such oral stories are the ways and means of a society to understand and be united with its past and present and future.

Oral literature has its roots in the consciousness of the western experience and can be traced back to the Assyrians, Hittites, and especially the Greeks. The

works of Homer are the commutation of the oral tradition that tells the story, in oral literature fashion, of the great Mycenaean empire, the Trojan War, and the odyssey of Odysseus. In ancient Rome, part of the oral literature was the combined works of Virgil, a collection of stories and adventures of Aeneas, the Trojan father of Romulus and Remus, the ancestors of the Roman republic.

Oral literature can be both stories that tell a history and the myths and legends that a people believe explain where and how they came to be. For example, in one Native American creation myth, White Buffalo Calf Woman gave the seven nations tobacco, maize, and the sacred pipe ceremony. Implicit in the oral literature of North American indigenous peoples are the understanding of the earth's spirit and the place of the human being in this delicate balance.

Oral literature, oral histories, and the oral tradition is a rich fabric of personal stories, legends, morals, and oftentimes the history of a people that transcends time and place.

ORALITY AND ANTHROPOLOGY

Orality, a term used in anthropology to interpret the performances of “verbal art,” was not a term created or defined by anthropologists for their particular use. It is a very old concept, formulated as the opposite of “literacy,” and has a long history in the humanities. It is encrusted with many beliefs and ideas that apply mostly to verbal art in Western societies with alphabetic writing systems. Thus, the tools used by anthropologists were created for one purpose, while anthropologists in the field must try to use them for another. A brief examination of the term's history will

clarify why “orality” as currently understood is a problematic notion.

Orality was framed as the opposite of literacy, not by modern authors but by Roman scholars active during the first century B.C.E. The virtues and characteristics of written texts had been molded earlier by Alexandrian scholars between the third and first centuries B.C.E. Scholars and researchers hired by the Greek pharaoh Ptolemy I to fill his libraries were confronted with a high volume of scrolls. In order to cope, the scholars were forced to become critics (lit.: “choosers”) and to select, to emend, and to create exemplary texts fit to belong to the “first class,” or “classics.” Discussions always revolved around the Homeric texts; many scholars of the time wrote learned commentaries, now mostly lost. Textual fixity (i.e., unchangeability) turned into the norm, not the exception. Cicero (1st century B.C.E.), the famous Roman orator, argued that the Homeric poems were a collection put together by the Athenian statesman Peisistratus during the fifth century B.C.E. The 1st century C.E. Jewish author, Josephus, living in Rome, pointed out in his *Against Apion* (a famous Homer scholar) that the Homeric texts (the *Iliad* and *Odyssey*) probably were recorded quite recently: “[Homer’s] date . . . is later than the Trojan war; and they say that even he did not leave his poems in writing. The scattered songs were at first transmitted by memory, and not united until later; the numerous inconsistencies of the work are attributable to this circumstance.” Josephus contrasted the famous epics with the Hebrew texts, whose origins were known to be very old (2,000 years, he claims), transmitted in writing from father to son. Josephus’s goal was to discredit the high esteem in which all things Greek were held by the Romans. He did not achieve this goal, but his (and Cicero’s) claim that the Homeric poems were a collection of fragments put together during the fifth century B.C.E. became part of common knowledge. There are numerous references to Homer in earlier Greek authors, but none state as clearly as Josephus that the poems must have been orally transmitted (although many modern scholars read this into these texts).

After the fall of the Roman Empire, the invasions of the Barbarians, and above all, the conquest of Christianity over paganism, the Homeric poems fell out of use in the West. The epics were copied and preserved in the East, in Byzantium. The Renaissance brought them back, but few people knew Greek, so

their difference in style and content did not immediately strike readers. But during the late 17th century all that changed: scholars began to comment that the Homeric poems were very unlike the Latin ones with which they had grown up, and the “oral origins” of the poems once again came to the fore. The 18th-century *Battle of the Ancients and the Moderns* in France (which spread to all European intellectual centers) was provoked by some authors defending Homer and his style, whereas others believed him to be outmoded. A few generations later, the Romantic reaction allowed the poems back into polite society, but under a different banner: now, they were considered to be similar to the primitive poetry of the natural peoples whose lives and ways were just being discovered in the Americas, except, of course, that the Greek poems were more complex and lengthy. The final connection between “primitive and oral,” and “civilized and literate” had been made.

As in antiquity, classical scholarship and biblical scholarship remained closely connected: many scholars, afraid to work on the Bible, worked on Homer instead. Methodologies and interpretations were borrowed; for instance, the arguments made by Spinoza in his *Tractatus Theologico-Politicus* (1670) about the interpretation of biblical texts are echoed in the 18th by Gianbattista Vico, whose oeuvre, *La Scienza Nuova Segunda* (1744), examined the Homeric texts for similar information and conclusions about human societies and their relationship to the divine. In the second half of the 18th century, a German biblical scholar, Johann Eichhorn, worked on the text of the Old Testament, separating out the “original” sayings of the prophets and their meaning and purpose from what he believed to have been added at a later date. His methodology, “higher criticism” combined with exacting philological analysis, was borrowed by Friedrich August Wolf, a German Homerist who carefully (in Latin) in his *Prolegomena ad Homerum* (1795) laid out all the “evidence” from the ancient texts to prove that Homer was an oral poet. During the 19th century, more evidence about orality was gathered from the new worlds and populations. Each new population provided more evidence that “the illiterate sang” whereas the literate and civilized composed in writing. Meanwhile, Homerists spent their time eliminating verses and stories that they assumed to have been added to the epics at a later date. Very quickly, “literate” and “civilized” always came to mean alphabetic literacy and Western civilization. Homer,

however, was never fully labeled as primitive; he remained a genius, the ancestor of Western literature, equal to the prophets of the Bible.

When, during the last half of the 19th century, anthropology slowly established itself as an independent and separate discipline, assumptions about orality and literacy were not reconsidered or recalibrated, possibly because they were so deeply ingrained in the worldview and belief system of the time. In addition, many of the early anthropologists had received a classical education and had internalized Greek and Roman classificatory systems and concepts.

During the 1920s and 1930s, orality and the oral origins of Homer once again were brought to the attention of scholars. Again, the impulse came from classics. An American classicist, Milman Parry, moved to France to obtain his Ph.D. In Paris he came into contact with the structuralist scholarship of Saussure, with its emphasis on spoken language. He similarly was influenced by the work of Lévy-Bruhl and his studies of the primitive mind. One of his mentors put him in contact with a Yugoslav scholar, Matthias Murko, a professor of linguistics at the University of Prague and a member of Jakobson's Linguistic circle. After his return to the U.S., Parry proceeded to compare the style of the oral performances of Yugoslav illiterate performers with that of the Homeric poems. The use of formulas, themes, meter, and so on appeared to confirm the earlier hypotheses that Homer's poems were oral poems. The oral characteristics, Parry argued, had been preserved by a recording in writing shortly after their (oral) composition by a master singer (Homer?). It was generally believed that oral characteristics would be lost after the arrival of literacy, an event thought to have occurred in Greece between 800 and 750 B.C.E. The comparison of ancient Greek poetry of uncertain provenance with the productions of illiterate performers of early 20th-century Yugoslavia was grounded in the evolutionist belief that human societies move through different phases, and in the unity of the human mind: pre-literates function in one way, literates function in another. It is thus that ideas stemming from antiquity received a modern blessing and confirmation. Initially, the Parry/Lord hypothesis seemed to solve many conundrums, such as the origins of the *Chansons de Geste*, or poems such as *Beowulf*, all created during the early Middle Ages, when writing was a skill limited to clerics and some bureaucrats.

Increasingly, however, it is becoming clear that the verbal art of other (non-Western) peoples cannot be made to fit into an "oral theory" derived from two millennia of Homeric and Biblical scholarship. The most telling counterexamples come from areas such as India and Southeast Asia, where literacy has coexisted for a long time with oral improvised performance. The advent of literacy does not seem to have affected the "orality" of the millennia-old epics, the *Ramayana* and *Mahabharata*, which continue to flourish and expand, both in written and in oral forms, while textual fixity is nonexistent for either poem. To accommodate such cases, anthropologists have attempted to represent orality and literacy as points on a continuum rather than opposites, but even with such adjustments, the underlying evolutionist line of reasoning still seems to suggest that the oral mind works one way, and the literate in another, and that all oral works eventually will achieve fixity due to their being written down. Anthropologists working in oral societies (i.e., where alphabetic writing is slowly introduced, usually by Christian missionaries) report a different set of problems, whereas scholars in South and Central America, where indigenous writing systems were systematically destroyed by the Catholic missionaries during the 16th and 17th centuries, present another. The oral performances of Native Americans as well as those of African singers are also difficult to fit into the oral theory as currently defined.

ORANGUTAN-HUMAN EVOLUTION

A PERSONAL REFLECTION

In the fall of 2000, I attended a seminar on primate evolution at Pennsylvania State University by a renowned primate paleontologist. The lecture was unremarkable until the subject of evolutionary relationships between humans and great apes. His reference to the chimpanzee as the natural choice seemed almost too obvious to need any particular justification, as the relationship is consistently presented throughout the popular scientific literature, textbooks, television, and movies as a virtually undeniable and established fact. But the speaker then chose to make a most unusual comment. He noted that the chimpanzee relationship was accepted by all except a "lunatic fringe" who favored the orangutan.

This colorful label in an otherwise straightforward presentation perked my ears up. I have learned over the years that few subjects in science are closed, and I was intrigued by this obscure reference to an alternative view. Over the last two decades, I contributed to changing the scientific landscape for the discipline of biogeography, which involved the exploration and promotion of views that were widely denigrated by prominent specialists. Through my research activities, it was necessary to consider the spatial evolution of many animal and plant groups, including humans. I therefore found the speaker's strange reference to orangutans too intriguing to be ignored without examination.

The culprit responsible for the lunatic fringe was not named, but I had an idea who it might be. By coincidence, my wife had found a book titled *The Red Ape: Orang-utans and Human Origins* in a Pittsburgh used bookshop nearly a year earlier. Due to her own interest in primates, her eye caught the title, and she thought it might be relevant to my biogeographic interests in human evolution. The jacket synopsis said the book offered "persuasive evidence that our closest relative is neither the chimpanzee nor the gorilla but the orangu-utan." I did not think much about it at the time. My wife bought the book nevertheless. Following the

lecturer's comments, I felt compelled to now take a good look at *The Red Ape* for myself.

I admit, I almost expected an assortment of miscellaneous conjectures and circumstantial arguments that so often populate unorthodox compilations. Here, I was in for a surprise. The author, Jeffrey Schwartz, was a professor of primate evolution at the University of Pittsburgh. In *The Red Ape*, he presents a sequential and coherent account of his investigations into human origins and a detailed outline of the evidence in support of our orangutan relationship. I was impressed by his professional argument based on accepted principles of systematics by which uniquely shared characters (traits) are the accepted standard for identifying evolutionary relationships between species. I was also intrigued to read how earlier studies involving fossil hominids had led to a very different conception of human ancestry from the now popular chimpanzee model.

Schwartz explained how prominent primate paleontologists such as Richard Kay, Martin Pickford, David Pilbeam, and Elwyn Simons once believed the 11-million-year-old fossil ape *Ramapithecus* (later subsumed under the name *Sivapithecus*) represented a direct human ancestor. Fossil fragments comprising the jaw and teeth exhibited several characteristically human-like features, including low molar and premolar crowns and flat chewing surfaces. We also find these in modern humans, and they therefore place the ape within the human lineage. When the facial region of *Sivapithecus*'s skull was later discovered, it looked—to everyone's surprise—more like an orangutan than an African ape, which had been the accepted model for human origins. Schwartz pointed to this particular discovery as a major historical turning point, confronting paleontologists with two alternatives: Either the orangutan was more closely related to humans than previously thought or *Sivapithecus* was no longer closely involved with human origins. Because there was already a widespread acceptance of humans having evolved from ancestors of African apes, paleontologists favored the latter alternative, and they banished *Sivapithecus* from human ancestry without further debate.

With *Sivapithecus* and orangutans separated from human origins, the presence of thick dental

enamel and flatted molars could no longer be accepted as evidence of evolutionary relationship because this also applied to orangutan teeth. Because the molars of African apes have thin enamel and a higher surface than either humans or orangutans, orangutan teeth were explained as the result of chance convergence. Schwartz challenged this conclusion by pointing to another possibility—that the shared dental characteristics are really evidence of a close evolutionary relationship between orangutans and humans. Was it possible, Schwartz asked, that *Sivapithecus* and orangutans together formed part of a larger group more closely related to humans than either of the African apes? To answer his own question, Schwartz set about determining whether and to what extent other features paralleled the dental similarities. In several publications, he detailed 14 characteristics that were exclusively shared between humans and African apes, less than the 17 characteristics restricted to just the African apes and far less than 35 characteristics that he found exclusively shared between humans and orangutans. The orangutan-human characteristics ranged from obscure differences in skeletal structure, such as the single incisive foramen in the upper palate, to prominent differences in bone formation, shoulder girdle structure, reproductive hormone levels, and brain asymmetry.

The total number and the range of human and orangutan characteristics were quite impressive, particularly in comparison with the chimpanzee, where proposed uniquely shared features with humans are often much less, ranging from 21 to as little as seven. What really caught my imagination was the way in which the orangutan characteristics could radically change theories about the evolution of human structure and biology. Schwartz contrasted the unique forelimb structure of African apes that allows them to walk on their knuckles with the absence of any supporting evidence for knuckle-walking in humans, orangutans, or any of the proposed fossil human ancestors. Another major difference between humans and African apes is the presence, at birth, of thickened or keratinized pads on the buttocks in many chimpanzees and gorillas. This feature is found in all other Old World primates with the sole exception of humans and orangutans. Before reading Schwartz's work, I had wondered

about the lack of beard and mustache in chimpanzees, since facial hair is such a prominent characteristic of male humans. Male orangutans also grow a well-developed beard and mustache—a condition otherwise absent among primates.

Absence of prominent African ape features in humans could be attributed to their evolutionary loss after the two groups separated, but this fails to anticipate the range of unique similarities shared between humans and orangutans. When we consider how these similarities encompass significant aspects of human biology and reproduction, it is increasingly difficult to find justification for dismissing the orangutan theory. In particular, a chimpanzee relationship seems to make nonsense of human reproduction. Female chimpanzees and gorillas, like mammals in general, have a physiologically focused period of mating called *estrus*. This coincides with ovulation and a correlated anatomical condition of genital swelling. Humans, in contrast, have concealed ovulation where genital swelling is absent during the menstrual cycle and mating patterns are not keyed by anatomical modifications. The human pattern appears to occur in orangutan females where genital swelling occurs only during pregnancy. Other reproductive similarities between humans and orangutans include the highest concentrations of the reproductive hormone estriol, and, when adjusted for body weight, a nearly identical gestation period that is longer than any other primate.

The numerous morphological and physiological characters shared between humans and orangutans indicate that Schwartz's theory was a robust alternative to the chimpanzee model and one that merited serious consideration. I reviewed the literature to find the critical response. To my surprise, Schwartz's evidence was barely acknowledged. Of the limited response, the most extensive came in some book reviews of Schwartz's orangutan book. Andrew Hill said that, while Darwin had Huxley as bulldog to promote and support his theory, Schwartz has yet to find as much as a poodle. Colin Groves actually accepted more orangutan shared characters as valid than he had found for chimpanzees, but then dismissed the orangutan theory as science fiction. These comments seemed to say more about the nature of

scientific debate in primate anthropology than any necessary deficiency in the orangutan theory itself.

I found the molecular genetic relationship to be the most often cited and repeated evidence for deriving humans from a common ancestor with the chimpanzee. Molecular techniques emerged during the 1960s, and, by the 1980s, they replaced the old, classical morphology to become the authoritative evidence for evolutionary relationships between living primates. Geneticists argued that noncoding regions of DNA were less prone to error from selection and, therefore, more reliable than morphology. This argument is contradictory, Schwartz noted, because genetic relationships were originally justified by their close match with well-established morphological relationships, relationships that were now seen to be unreliable. Another problem was the absence of any way to know which genetic characters were uniquely shared without constructing a phylogeny in the first place. Genetic methods might produce consistent results, Schwartz argued, because they represented overall similarity in DNA base sequences due to primitive retention or convergence rather than different sets of uniquely character relationships associated with evolutionary relationships as one can identify in morphological approaches.

In an attempt to resolve the conflicting views on orangutans, morphology, and genetics, I contacted several prominent primate researchers to find out how they explained the orangutan evidence. A molecular researcher chided me for taking any interest in the orangutan theory and expressed some alarm that I was considering the subject suitable for public information. I was told that the chimpanzee relationship was proven by genetic studies, and that was all there was to it. Three paleontologists declared that morphology was so unreliable that we had to accept the molecular evidence, although they declined to explain how they could know, in the absence of genetic evidence, whether the fossil ape taxa they studied were related to humans. When I asked the speaker who had originally prompted my interest to justify his confidence in genetics that proved the chimpanzee relationship, he had to ask a molecular colleague, as he could not explain it himself. And neither could he explain how his paleontological research on hominids remained valid if we could no

longer rely on morphology to predict human relationships.

I also contacted some prominent morphological systematists who supported the chimpanzee relationship. I found their studies problematic because they did not address the proposed orangutan characters, and their evidence for a chimpanzee relationship was weak. Over a 10-year period, for example, Colin Groves at the Australian National University reduced his own chimpanzee-human characters from 25 to six. An orangutan ecologist expressed her alarm about a Buffalo Museum of Science exhibit on the orangutan theory because it had been rejected by the so-called anthropological community. The only exception to this general pattern of routine resistance was Ian Tattersall of the American Museum of Natural History. He suggested to me that the general unwillingness to even consider the notion of humans being more closely related to orangutans than African apes is testimony more to the power of received wisdom than it is to the power of the evidence. He also wondered whether the resistance would have been so strong if Darwin had not backed the African apes in the first place.

The more I looked at the available morphological evidence, the more the orangutan relationship appeared better supported. If Schwartz's evidence was so weak to justify such summary dismissal, I expected to see substantial contradictory morphological evidence, particularly in the fossil record. According to molecular reconstructions, humans evolved from a common ancestor with chimpanzees as recently as 6–7 million years ago. This model led me to consider the oldest members of the hominid ape genus *Australopithecus* to exhibit more than a passing resemblance to chimpanzees and certainly provide some definitive African ape characters. Instead, it appeared that these hominids bore a more-than-passing resemblance with orangutans. The most prominent similarity is the broad, forwardly facing cheekbone, quite unlike the chimpanzee where the ventral surface of the cheekbone slopes away. The facial region across the eyes is also vertically flattened like the orangutan (and incidentally, like *Sivapithecus*) rather than forming into a concavity in the chimpanzee. Australopiths do have prominent brow ridges, as do some later hominids, and some systematists have

identified this with the prominent brow ridges of chimpanzees. Schwartz pointed out that the brow ridge of chimpanzees and gorillas forms a forwardly projecting bar above and between the eyes with a prominent channel or sulcus immediately behind. Neither the bar nor sulcus is present in the orangutan or in *Australopithecus*, where the brow ridge is confined to an upraised area above each eye, much like the orangutan.

A sense of clarity is something that we may expect of a good theoretical model and yet the nearly absolute confidence in the chimpanzee model belies the confused picture of hominid origins. A recent *Scientific American* article noted that researchers cannot agree over what makes the human lineage unique, and they even have trouble defining hominids. Hominid characters at the beginning of the human lineage are elusive and increasingly so the closer we get to the supposed last common ancestor with chimpanzees. With all this confusion, I cannot help but wonder if these problems are somehow more a function of looking for the wrong ancestor.

The orangutan model may provide paleontologists with opportunities for developing clarity about human origins. The fossil apes *Sahelanthropus* and *Ardipithecus*, both widely portrayed as hominid ancestors on the basis of very tenuous evidence for bipedalism, may not be hominids at all because they lack thick dental enamel and low molar cusps. In contrast, the thick molar enamel claimed for *Orrorin* from Kenya would be congruent with being a member of the human-orangutan group. Other possible candidates for the human-orangutan lineage include the thickly enameled *Kenyapithecus* (East Africa, 16 million years), *Ouranopithecus* (Europe, 9 million years), as well as the orangutan affiliated *Sivapithecus* (Central Asia, 14 million years), *Gigantopithecus* (2 million years) and *Lufengpithecus* (East Asia, 8 million years). The modern relationship between humans and orangutans may, therefore, represent the surviving eastern and western remnants of a formerly diverse ancestral group spanning Africa, Europe, and Asia at least 16 million years ago.

By the time I reached these conclusions, I decided that the contrasting theories of human origin would complement the primate exhibit at the Buffalo Museum of Science. The museum already

displayed a replica of the famous 3.2 million-year-old *Australopithecus afarensis* skeleton known as Lucy. An artistic reconstruction prepared in 1987 by scientific illustrator Bill Parsons followed established conventions and showed a face with the appearance of an African ape, including soft tissue features such as the broad, fleshy nostril and short cranial hair with a hairline close to the eyebrows. Artistic representations of hominids continue to follow this protocol, partly because of how australopithecine skulls were often represented. There are only a few skull fragments of Lucy available, so the question of how they fit together is a matter of some conjecture. The popular reconstruction that shows similarities to the chimpanzee now face critical challenge through a recent reconstruction for another specimen of *Australopithecus afarensis* that shows a relatively high domed cranial vault, more like an orangutan in profile than a chimpanzee.

I asked artist Bill Parsons to render another representation of Lucy in light of the new skull reconstruction and in consultation with Jeffrey Schwartz. When Bill followed the form of the skull, the result was a facial shape fully consistent with an orangutan appearance. This similarity was enhanced by the addition of soft tissue features uniquely shared between orangutans and humans. The cranial hair was longer and oriented forward (a feature common to humans and orangutans), the hairline was high on the forehead (unique to humans and orangutans), and the nostrils lacked the fleshy extension found in African apes. A dense covering of body hair was included, but this is an entirely conservative speculation. Last, but not least, Lucy was given that enigmatic closed-mouth smile so characteristic of humans and sometimes seen in orangutans.

I was beginning to see that the common ancestry with orangutans would lead to some very different speculations about our immediate ancestors. For example, the recent BBC film *Walking With Cavemen* reduced Lucy's species to the condition of a frenetic, agitated, and gregarious social life dominated by aggressive, polygamous males. Orangutans are famous for their isolated social lives, yet recent studies indicate a more complex pattern of social cohesion involving dispersed social groups and long-distance

vocalization. As a bipedal, orangutan-like hominid, Lucy may have lived in a group that was far less communally ordered than that of the chimpanzee; her social relationships may have involved a spatially dispersed cooperative group more like orangutans and modern humans. Communications between dispersed individuals may have employed artificial means of amplification, as observed in orangutans where hands or leaves are used for this purpose. Human children also often use the latter technique.

Other features found in both orangutans and humans led me to consider specific predictions about the possible biology—and even psychology—of early hominids. As an individual of about 20 years, Lucy may have already given birth—an event that may have involved assistance from her mate or other members of her group. This practice of what is effectively a midwife function in humans has been observed in some orangutans in captivity.

It is also possible that sexual behavior included face-to-face mating with sustained periods of copulation unrestricted by ovulation cycles, all features found in both humans and orangutans. Even the practice of using artificial aides for sexual arousal is present in the orangutan and may, therefore, be expected to already be present at the beginning of human evolution. Lucy may have also engaged in mate choice or even experienced mate jealousy as found in orangutans. As an adult, Lucy may have been involved in long-term pair bonding as an extension of the orangutan pattern where females may reestablish consort relationships with the same male after a child-rearing interval of many years. This expression of mate fidelity may anticipate a hominid social structure that included family units comprising the presence of both parents and offspring. Like orangutans, Lucy would be expected to engage in long-term child care, and, as a teenager, Lucy may have exhibited her most gregarious social interactions as found in both humans and orangutans.

Lucy's source of shelter, whether on the ground or within trees, may have taken the form of housing that included roofing as protection from rain or sunshine as well as personal protection in the form of leaf umbrellas, as found in orangutans. Her sense of artistic creativity may be anticipated by aesthetic expressions found in orangutan designs, such as

artistic "pillows" whereby orangutans use similar twigs to line their nests, sleeping with leaf bundles (dolls), or personal adornment or ornamentation using foliage, a practice also found in gorillas. Finally, we would expect the ability to form a complex tool kit that involved a range of functions, as we find in both chimpanzees and orangutans, with both sexes being involved in their construction. Even without the use of stone tools, we must consider the possibility of the development of wooden spears, because the ability to strip stems of leaves and throw them is found in orangutans.

As long as we leave orangutans out of our consideration in understanding human origins, we must also dismiss out-of-hand the disturbingly "human" qualities of orangutan morphology and biology as mere curiosities. That they continue to be dismissed in this way by all but two primate evolutionists does not appear to be justified by the available morphological facts. While the veracity of some or all of the features that point to the orangutan could be contested, the genetic and morphological arguments for the chimpanzees relationship are also open to critical doubt. It is clear at the very least that the morphological evidence raises critical questions about the prevailing popularity of the chimpanzee theory. The weight of morphological similarities between humans and orangutans is far stronger than between humans and chimpanzees, and the fossil record shows what are disturbingly orangutan-like similarities. At the very least, Schwartz presents a substantial case. The more I look at the orangutan, the more I find myself looking at a mirror where the past becomes the present.

ORANGUTAN ECOLOGY AND BEHAVIOR

Wild orangutans are now found only in the lush, swampy forests on the islands of Borneo and Sumatra in Indonesia. In prehistoric times, there were huge orangutans that roamed over Asia. The genus *Gigantopithecus*, the largest fossil ape known to science, is related through primate evolution to the living orangutans of today.

The orangutan is the only great ape of Asia. Like the three African pongids (bonobo, chimpanzee, and gorilla), the orangutan is a vanishing animal threatened with extinction. This is primarily due to two factors: the wanton destruction of its natural environment as a result of the encroachment of human civilization (especially by loggers and miners) and the poaching of this so-called red ape for the purpose of selling orphaned infants on the black market after their adults have been killed. If serious and immediate measures are not taken, wild orangutans may become extinct by the middle of this century.

To understand and appreciate orangutans in their natural habitats, several primatologists have focused their research on studying this pongid on the islands of Borneo and Sumatra. Knowledge about the ecology and behavior of this shaggy red ape is necessary to enhance those methods that are dedicated to preventing the extinction of this great ape.

Having been encouraged by anthropologist Louis S. B. Leakey, Biruté Mary F. Galdikas has devoted her professional career to the study of orangutans for the specific purpose of saving them from extinction. Her books and lectures, based on close-range and long-term research on Borneo, have added invaluable information about this red ape of Asia. Camp Leakey is her fitting tribute to the anthropologist who had realized that studying the great apes is

crucial to comprehending the origin and evolution of our own species.

Orangutans spend most of their time in the trees. They are, in fact, essentially arboreal and semi-solitary. The relationship between mother and infant is a temporary one over a period of five years. Large adult males will come to the ground, spending much time shambling along the forest floor before climbing back into the trees. Peering down from the forest canopy, their faces resemble those of human beings, a characteristic that has earned the orangutan the informal title of "person of the woods."

Although they build nests in the trees or on the ground, orangutans do not live in complex structured societies or exhibit group social discipline. Adult males and females are primarily asocial or live in loose social groups. There is no family unit or lasting relationship between an adult male and an adult female. Orangutans spend much time feeding, resting in nests, and leisurely moving through the trees of the dense tropical jungles. They rarely groom each other and are usually silent. However, the powerful adult male will attract adult females by making a long shrill call when he releases air from his throat sac (gular pouch).

The orangutan diet is essentially frugivorous and includes buds, shoots, nuts, seeds, honey, soft bark, wood pith, young leaves, flowers, and insects, as well as wild unripe and ripe fruits but very rarely meat. Orangutans will use sticks to extract honey from bee hives in trees. Both in terms of their biology and behavior, these apes have adapted to life in the trees over thousands of years. Unfortunately, in captivity, the orangutan is lethargic and therefore prone to obesity and, consequently, the possibility of early death.

Because the orangutan is one of the four pongids, it is not surprising that this primate shows many biological similarities to the human animal. In fact, some scientists claim that our own species is closer to the orangutan than it is to the bonobo or chimpanzee or gorilla. This hypothesis encourages more research into the physical characteristics and behavior patterns of this Asian great ape.

In Pongoland at the Leipzig Zoo, visitors will see orangutans living in a large, natural forest-like habitat that allows these apes to roam freely. The project is sponsored by Germany's Max-Planck-Institute for Evolutionary Anthropology. Along with DNA databases preserving the genetic information of pongids

as well as other primates, such exhibits help ensure the survival of the orangutan and the other three great apes.

The wild orangutan is a gentle, independent, and free-ranging ape. It lives a somewhat lonely existence in the rain forest canopy and, until recently, was isolated from human civilization. The ongoing studies of Galdikas and others will help to protect this unique pongid from abuse and extinction.

ORANGUTAN SURVIVAL, THREATS TO

The last populations of orangutans are in dire straits and possibly face extinction within the next few decades. Over 80% of wild orangutan populations live in Indonesian Borneo and Sumatra, while 20% or less are found in Malaysian Borneo. The survival of orangutans is threatened by massive habitat destruction, forest degradation, and forest fragmentation. Orangutans are arboreal and totally dependent for long-term survival on forest. The establishment of large palm oil concessions carved out of remaining forests, as well as widespread illegal logging, especially in Indonesia's reserves, protected forests, and national parks, may spell doom for the orangutan species in the wild. The future of wild orangutans is tied to the fate of Indonesia's and Malaysia's forests.

Past estimates for orangutan populations in the wild have ranged from 15,000 to 30,000 individuals, but recent surveys and better census methodologies have indicated that as many as 50,000 orangutans

may still survive in the wild. The largest populations are found in Tanjung Puting National Park and the recently (2004) declared Sebangau National Park in the Indonesian province of Kalimantan Tengah (Central Borneo). Each of these two parks contains about 6,000 orangutans. The most recent estimates for Sumatra indicate that only 7,000 orangutans remain in the two Indonesian provinces of Aceh and North Sumatra. As in Borneo, massive deforestation and the killing of orangutans as agricultural pests and for food are responsible. Orangutan females are also killed for their infants, who are sold into the pet trade. However, this trade is very opportunistic and closely tied to the opening up of rain forests.

Indonesia's tropical forests are the second largest in the world, after those of Brazil, and, as of 1995, covered at least 100 million hectares. Indonesia boasts about 10% of the world's remaining tropical forests. But the recent decline in Indonesia's forests is very dramatic. More than 1% of Indonesia's and Malaysia's forests have been lost each year over the past decade. The conservative figure for Indonesia's loss of forest is a rate of 1.3 million hectares per year.

The establishment of palm oil plantations at the expense of native forests is probably the most important direct cause of orangutan population loss. Plantations are increasing at the rate of 3% per year, and a large proportion of this consists of plantations of the African oil palm. Malaysia and Indonesia together produce over 95% of the world's palm oil. In Indonesia, most of the new plantations are being opened up in Kalimantan (Indonesian Borneo) and Sumatra. Of the 1.3 million hectares of forest lost each year in Indonesia, at least 330,000 hectares are lost through the establishment of palm oil plantations.

The widespread presence of unregulated and unsustainable logging, both legal and illegal, throughout Borneo and Sumatra also threatens orangutans. In Indonesia, illegal logging, much of it from parks and protected areas, is the primary source of logs, accounting for at least 52% of the total. In Kalimantan Tengah, illegally logged timber may account for up to 70% of the total.

In addition to being killed as pests—particularly when they, as refugees from destroyed forests, raid plantations for food—orangutans traditionally have been eaten by Dayaks as a source of bush meat. Although this hunting is not commercial, the greater availability of firearms and the decrease in forest

cover makes orangutans much more vulnerable than these animals were in the past.

Orangutans face another threat: fire. Massive forest fires during droughts exacerbated by the El Niño weather phenomenon have destroyed large areas of forest, as much 2.7 million hectares in 1982 and 10 million hectares of forest, woodlands, and grasslands in 1997. Historic accounts indicate that El Niño is a periodic weather phenomenon that was associated with droughts and small, naturally caused fires in the

past. However, in the last few decades, massive forest clearing in Borneo and Sumatra to establish plantations and a rapid increase in illegal logging have left huge fuel loads of dead branches and other dry wood litter on forest floors. The presence of this dry timber has led to enormous fires, which proved to be disasters of epic proportions for orangutans and other wildlife.

In association with these fires, the Rice Bowl Project was disastrous for orangutans. This project was initiated in 1995 to convert one million hectares of peat swamp forest into a major rice-growing region of Indonesia—in an area that held, at the time, probably the largest wild orangutan population in the world. The 1997 El Niño drought, intentional burning of the one million hectares of forest, timber waste from reckless illegal logging, and intentional drainage combined to produce unmitigated disaster that left thousands of orangutans dead. Fortunately, the project was abandoned a few years later.

To ensure the survival of orangutans as biologically viable populations in Indonesia and Malaysia, it is essential that the enforcement of laws dealing with the protection of endangered species be implemented in a consistent and firm way. The killing and capture of orangutans should be punished with jail sentences and fines. Hopefully, local people will be educated to view conservation and wildlife protection as moral issues. The establishment of more

protected areas where entire orangutan populations can be protected from human encroachment is also a very important measure needed to save orangutans from extinction.

ORANGUTANS

Orangutans are great apes of the genus *Pongo*; they are the largest living nonhuman primates after gorillas, and one of the most critically endangered. They live only on the islands of Borneo and Sumatra, in Southeast Asia. They are found over most of Borneo,

but in Sumatra they are restricted to the northern quarter, with a few isolated populations some way down the west coast. The name is a corruption of *orang hutan* (“forest-living person”) and may originally have designated tribal people such as the Penan of Borneo or the Kubu of Sumatra, but it became commonly used in Europe to refer to any ape. Most indigenous peoples refer to them as *mawas*.

Orangutans have sparse reddish hair covering dark grey skin. The arms are longer, compared to the legs, than any other primate: the intermembral index (arm length as a percentage of leg length) varies between 135 and 150%. The face is strongly prognathous (the jaws jut forward); the profile varies from concave to nearly straight; the orbits are tall and oval, without supraorbital tori (thickened brow ridges); the forehead is round and ascends at about 60° behind and above the orbits; the braincase is short, high, and rounded. As in other great apes (gorillas and chimpanzees), the canine teeth are relatively long but thick in males and shorter and smaller in females, but unlike other great apes, the orangutan’s upper central incisors are expended and spade-shaped, while the lateral incisors are thin and pointed. The molar teeth are large and flat, with thick enamel that is minutely wrinkled. Fully grown male orangutans weigh from 80 to 91 kg, adult females less than half of this, from 33 to 45 kg.

Genetically, orangutans differ from gorillas, chimpanzees, and humans by about 3.1%, implying that their ancestors separated from them before they separated from each other; in other words, orangutans are the third most closely related ape to us. These phylogenetic relationships are recognized by placing them all in the family Hominidae, but in different subfamilies: orangutans belong by themselves in the subfamily Ponginae, while gorillas, chimpanzees, and humans belong in the subfamily Homininae.

Bornean and Sumatran orangutans are very different and are today placed in different species. The Sumatran orangutan (*Pongo abelii*) is taller and leaner in build, the hair is usually gingery in color (though there is some variation in this), and the face is covered in light downy hair and is an elongated oval shape. The Bornean orangutan (*Pongo pygmaeus*) is shorter and fatter, the hair is usually dark maroon, and the face is hairless and figure-8 shaped, with deep hollows under the cheeks. The chromosomes have characteristic differences. Molecular clock calculations suggest that they may have separated as much as 1.5 to 2 million years ago.

Orangutans are almost wholly arboreal—except, perhaps, for some old Bornean males—and largely solitary. This does not mean that they lack a social organization; on the contrary, their social relations

are highly complex and reflect their prodigious cognitive skills, which seem to be barely, if at all, inferior to those of chimpanzees (like chimpanzees, some orangutans quickly learn to recognize themselves in mirrors). They feed mainly on fruit, falling back on figs during periods when fruit is scarce, and also eat leaves, bark (especially in Borneo), and insects (especially in Sumatra). In one study site, Suaq Balimbing in northern Sumatra, females occupy overlapping home ranges averaging 850 ha, whereas fully grown males have

much larger ranges, about 2,500 ha, which overlap those of both females and other males. In Borneo, these home ranges appear to be generally smaller. Females may associate together temporarily, but males do their best to avoid each other. Males who are not fully grown have similarly large ranges, and avoid the full-grown males. There are also nomadic males who may wander from site to site looking either for food or for fertile females.

They are very slow breeders. Their gestation period is about 240 days, and they give birth to a single young who is dependant on its mother for years. Both sexes become sexually mature at about 8–10 years. The interval between live births is perhaps the longest of any mammal—at least 6 years, and as much as 8 years in some populations. They may need this time to learn the complexities of life in the rain forest. In captivity, they may live well over 50 years; in the wild, they certainly reach considerable ages, but exactly how long they may live is not known.

The big males have flanges of connective tissue at the sides of the face, beards and moustaches (longer in Sumatran orangutans), and large throat pouches (bigger in Bornean orangutans). With the aid of the throat pouch, a male makes a booming call, which alerts females and rival males alike to his presence. The females are attracted to the big-flanged males and mate with them at midcycle; the menstrual cycle averages 29 days long. The males who are not fully grown, but are sexually mature, try to mate with females who are, however, unwilling; their attempts have been described as “rape”; in Borneo, even flanged males may force copulations in this way, but this is very rare in Sumatra.

Two surprising discoveries have been made recently. First is that these unflanged males—at least in the Sumatran species—are not necessarily subadult; they may remain in that condition for years, perhaps for their whole lives. It has been proposed that it is a way of avoiding the stress of maturing fully when a flanged male is around. Second is that, at least in one study site in Sumatra, unflanged males sire as many offspring as the big flanged males, so it is obviously a very successful alternative reproductive strategy.

Different orangutan populations have different cultures, just as do different chimpanzee populations. All orangutans make an aggressive sound called a “kiss-squeak”; in just two populations, both in Borneo, an individual will hold a leaf to the mouth to

amplify this sound. Only in the Suaq Balimbing population do orangutans use sticks to winkle out insects from tree holes. In one Borneo population it is customary to wipe sticky substances from the chin with a “napkin” of leaves. Each population is remarkably different and has built up its own culture over years or perhaps even centuries.

As recently as the Late Pleistocene, orangutans lived all over Sumatra, in Java, and on the mainland of Southeast Asia as far north as southern China. Today, they are crashing toward extinction. In historic times they are known to have inhabited only Malaysian Borneo (Sabah and Sarawak) and Indonesia. In Malaysia the numbers declined during the early 20th century but are today stable, if fairly low. The coming of democracy to Indonesia in the late 1990s was unfortunately accompanied by a breakdown of law and order, and illegal logging, forest fires, and clearing of land for oil palm plantations have destroyed much orangutan habitat, while hunting and the smuggling of young orangutans overseas have greatly increased. Although the situation is slowly coming under control, there will probably be very few orangutans remaining in five years’ time—perhaps none in at all in Sumatra. This will be a scientific, cultural, moral, and humanitarian tragedy.

ORANGUTANS IN CAPTIVITY

In early 2005, there were approximately 900 orangutans in captivity. Western Europe had the most, with 303, while the United States had 268. Most of them live in zoos.

Orangutans are very intelligent animals, and it can be boring for them to live in a cage at the zoo. Efforts are being made at most zoos to relieve that boredom by using what the zookeepers call enrichment. For example, when the Sacramento Zoo in California first obtained orangutans in 1965, the exhibit was a cement grotto with dry moats. In 1984, that grotto was demolished and modernized.

That exhibit continues to undergo changes through the years. Artificial trees and ropes are provided for climbing.

When animals live in the wild, they have lots of opportunity to make choices. In a traditional zoo atmosphere, all the choices are made for them—what they eat, when they eat, where they sleep, and so on. The Sacramento orangutans have an indoor area available to them when the weather is too hot or too rainy to be outside. They can make the decision as to where they want to be.

Enrichment programs provide the animals with novel experiences that stimulate and encourage the types of behaviors that would be typical of these animals in the wild. In the wild, almost half an orangutan's time is spent in foraging for food. Besides occupying time, this provides intellectual stimulation for the animal. Food in captivity is often provided in such a way as to encourage natural foraging behavior. In modern zoos, food is sometimes concealed in different places around the exhibit so the animal can look for it. Sometimes food is placed inside a puzzle that the animal has to manipulate in order to obtain the food. Using the puzzle feeder results in increased feeding-related behavior and more activity.

Besides being good for the animal, enrichment tends to make a visit to the zoo more enjoyable for the visitors. It's a lot more interesting to watch an orangutan swing on ropes, climb through trees, and manipulate a puzzle feeder than to watch it pace back and forth on a well-worn path. No program can duplicate the natural environment, but an enrichment program can provide opportunities and motivation for the orangutans to practice appropriate behavior, reduce stress, and generally improve the animals' physical, mental, and social well-being.

Orce is a Spanish village famous for the controversy regarding the supposed finding of the oldest Eurasian hominid: the Orce man. Orce is near the Venta

Micena paleontological site in the Guadix-Baza basin, Granada province, Spain. In 1982, a small cranial fragment was found in the Venta Micena excavation quarry and was published in 1983 as *Homo sp.* by Josep Gibert, Jordi Agustí, and Salvador Moyà Solà. They claimed that this fossil, unearthed from sediments 1.8 million years old, constituted the oldest hominid found in Eurasia and belonged to *Homo erectus* or even *Homo habilis*. Once the fossil was cleaned, in the inner face a prominent crest appeared, and the controversy began. The prestigious French paleoanthropologists, Henry and Marie Antoinette de Lumley, retracted their support of the hominid attribution. Agustí and Moyà Solà published a paper in 1987 concluding that the suture and the crest made impossible the attribution to *Homo* and the fossil was reattributed to *Equus*. Nevertheless, Gibert decided to maintain his attribution to *Homo* and began a controversial search for evidence and support.

The fragmentary fossil, popularly named the “biscuit,” given its small size and rounded form, was exhaustively analyzed. Domènec Campillo concluded, based on the contradictory morphology, that it belonged to an infant of the genera *Homo*. Enrique García Olivares also concluded, based on immunological analyses, that the fossil belonged to a hominid, but it was suspicious that a fossil so old contained such high quantities of human albumin. Paul Palmqvist studied the cranial suture using fractal analysis and also concluded that the fossil could have belonged to the genus *Homo*. However, Palmqvist soon realized that the oversimplified suture sent by Gibert was not real, accused him of fraud, and published another paper in the *Journal of Human Evolution*, reevaluating the evidence and concluding that the fossil may have belonged to a 3- to 5-month-old horse. The details regarding this controversy were reported in 1998 by Eustoquio Molina in the journal *El Escéptico*, concluding that this could be a case of pathological science.

The controversy was magnified by the mass media, where Gibert looked for support, making many sensational claims. Three outstanding Spanish paleontologists replied in a newspaper article, criticizing the Gibert methodology. As was stated long ago by David Hume, extraordinary claims demand extraordinary evidence (Occam's razor), however the evidence found by Gibert and his colleagues is not extraordinary but very suspicious and controversial. Consequently, the

most plausible attribution of the fragmentary fossil is to *Equus*, which is very abundant in the site, although based on a recent reinterpretation of the anatomical evidence by Bienvenido Martínez Navarro, it could be attributed to a ruminant, which is also frequent in the site. Nevertheless, Gibert still maintains the hominid attribution in his controversial book, *El Hombre de Orce: Los Homínidos que Llegaron del Sur* (2004). At present, few scientists believe Gibert's sensational claims, but he still has the support of his friend Campillo, who published another controversial book, *El Cráneo Infantil de Orce: El Homínido Más Antiguo de Eurasia* (2002).

The oldest fossil hominid remains in Eurasia cannot be the controversial fossil fragment from the Venta Micena site, which is not considered human. At present, the oldest human remains in Spain are those of *Homo antecessor* from the Trinchera Dolina site (Atapuerca) dated at 0.78 million years. Furthermore, the oldest hominid evidence is the lithic industry that has been recently found at the Sima del Elefante site (Atapuerca) and Barranco León-5 and Fuente Nueva-3 sites (Orce). This evidence is dated at about 1 to 1.3 million years, having been found just below Jaramillo in the Matuyama magnetochron.

OREOPITHECUS

One of the most controversial fossil primates known, *Oreopithecus bambolii* has generated substantial debate since its original discovery in the 1870s. Although only distantly related to humans, this Miocene hominoid shows several features that later evolved in parallel in the earliest human ancestors, including potential bipedalism and hand grasping ability. While its taxonomic placement and phylogenetic affinities have garnered controversy, scientists recognize *Oreopithecus bambolii* as an important species in understanding the evolution of certain human characteristics.

The first *Oreopithecus* specimens were discovered in the early 1870s in the lignite mines of Tuscany. In 1872, noted French anatomist and paleontologist Paul Gervais named these fossils *Oreopithecus*, which he described as similar to both gorillas and macaques. Much debate over the phylogenetic position of *Oreopithecus* soon followed, with some scientists arguing that the species was perhaps ancestral to modern humans and others pushing for a close linkage to the Cercopithecidae. A cache of additional specimens, including a complete skeleton of a young adult male, was unearthed near Baccinello, Italy, in 1958. Originally studied by Johannes Hürzeler, these specimens have settled much of the taxonomic debate. Although *Oreopithecus* “jumps around” in many modern cladograms, most researchers agree that this genus is a primitive hominoid closely related to *Dryopithecus*. Depending on which classification one follows, *Oreopithecus* may be placed in the Hominidae, but is far removed from humans.

Although known only from Italy and possibly Moldova, *Oreopithecus* is the best represented European fossil hominoid. Its fossils have been found in the Late Miocene sediments of Tuscany and Sardinia, which have been dated to 7–9 million years ago. During the Late Miocene, this region is thought to have been an island, and the insular environment of *Oreopithecus* is often cited as the source of many of its unusual features.

Oreopithecus was a relatively large-bodied primate, reaching sizes of 30–35 kilograms. Chief among its distinguishing features were a small brain, extremely short face, small postcanine and canine teeth, gracile carpals, and robust facial bones that indicate strong chewing muscles. The primitive and conservative

postcranium of *Oreopithecus* has often been described as similar to the ancestral hominid morphology, and several studies have shown similarities in dentition between this genus and modern hominids. Additionally, the strong chewing muscles and small brain of *Oreopithecus* suggest a strongly folivorous diet, although some scientists have disagreed with this conclusion.

Also controversial is the notion that *Oreopithecus* was a habitual biped with human-like hand-grasping abilities. Based on a study of the internal bone structure of the pelvis, along with an examination of leg and foot morphology, it has been suggested that *Oreopithecus* was bipedal, perhaps as a consequence of its insular environment. The development of bipedalism freed the hands of *Oreopithecus* from locomotion, which enabled the evolution of an improved grasping ability similar to that seen in modern humans. Although unrelated in an evolutionary sense, these features make *Oreopithecus* an important species for understanding human bipedalism and grasping abilities. However, the hypotheses of bipedality and grasping in *Oreopithecus* have not been met with total acceptance. Other scientists have argued that *Oreopithecus* was an arboreal form, and that its unique hand and hip morphology reflect ape-like power, grasping, and suspension, not bipedalism.

As material of *Oreopithecus* is well-known, disagreements such as these should extend into the near future. However, despite the frequent debates and controversy, scientists agree that *Oreopithecus* is an important early hominoid that reveals much about early human relatives and the evolution of certain human characteristics.

ORNAMENTATION

Ornamentation is decorating or beautifying objects or human bodies. Architecture is ornamentation on a larger scale; human beings alter their surroundings using artistic methods such as stained glass, textured walls and ceilings, and murals. Throughout history human beings have esthetically improved their surroundings. Ornamentation is present in physical objects such as pottery, textiles, and art. It is believed that the *Homo sapiens sapiens* were the first to sculpt animal and human figurines from ivory, engrave images on limestone blocks, and create ornamentation from ivory, shell, soapstone, and animal teeth. Tools and weapons have been found that appear to have originated 40,000 years ago, possibly to help construct personal ornaments. Cave art and paintings have been discovered at Lascaux dating back around 17,500 years, believed to be made by the Cro-Magnons. The site Sungir, located in Russia, shows signs of personal ornaments of ivory and schist carved into geometric and animal forms and dating back 28,000 years. Another site in Russia, the site of Kostenski 17 in the Don Valley, dates back 36,000 years and shows signs of ornaments constructed out of fossil coral and belemnites. With the advancement of technologies, both the pottery and textile industries have seen dramatic improvements. Although there have been many instances of extravagant items created from pottery and textiles in the past, new technologies continue to make the process easier and faster than before. Individuals use these artistic techniques to create functional objects, to express a certain characteristic about themselves or their culture, and to leave a footprint of human evolution. These expressions may be made consciously or unconsciously.

Humans adorned themselves from early ages. Human ornamentation involves decorating the body by wearing specific clothing, jewelry, headdresses, body paints, tattoos, body piercings, brandings,

scarifications, or cicatrizations. Decorating the body is a means to communicate and express a variety of meanings that are symbolic of the individual or his or her culture. Some theories associated with ornamentation suggest that certain adornment practices, such as tattooing, serve the purpose of closely connecting social and spiritual customs in a population. Certain cultures believe that the use or wearing of specific ornaments will protect them from evil spirits or bad luck. There is also a belief that body ornaments unify groups of people while placing them in certain geographical areas depending on the characteristics of the ornaments.

Jewelry

Different types of jewelry may be worn by people depending on their age or whether they are male or female. Jewelry is found all over the world, in different styles, colors, shapes, and made from diverse components. Many ancient societies created beautiful pieces from stones, shells, gems, rocks, wood, and precious metals. In Hawaii, personal ornamentation had great importance. Leis, worn to fend off evil spirits, were made from nonperishable and perishable objects. The nonperishable objects included stones, feathers, and shells. Perishable leis consisted of flowers, fruit, and leaves. Beaded necklaces are popular among African tribes. Most people in eastern and southern Africa wear some form of beaded jewelry, but in the western part of Africa, beadwork is reserved for members of royalty. The colors of the beads used, shapes, and patterns carry much significance. The type of necklaces worn in these societies can also communicate information about the individual. Women tend to wear their beadwork to illustrate their wealth. Depending on the number and types of necklaces worn, a woman may be seen as wealthy or not. Furthermore, wearing a specific beaded necklace tells other individuals in the society that the woman is nursing.

In India, jewelry plays an important role in ornamentation. Bangles, bracelets, or wristlets are popular among Indian women. It is the variety and number worn that expresses whether a woman is married or betrothed. It is also suggested that a woman wearing wristlets is able to express different emotions nonverbally by the tinkling sound they produce. Armbands and armlets are prevalent among Indian and Egyptian cultures.

Body Painting

Body painting involves decorating parts of the body using natural or artificial paints. In many cultures, body painting is used as a temporary disguise or simply to decorate the body. Henna is a popular source of paint in India and Egypt. Henna is often used to paint parts of a woman's body for traditional Indian weddings. The Australian Aborigines frequently use body paints during ceremonies and rituals. They decorate the body with patterns for protection, as a mark that the individual is in transition, and to aid in the recollection of dreams.

Headdresses

Headdresses are any objects covering the head partially or completely. They are made of various materials such as cloth, animal skin, or plants. In many societies, past and present, there are figures of authority or of specific importance who wear special headdresses. Warriors and shamans wear special garments to differentiate them from other members of the society and to command respect. In Western society, headdresses may identify figures of authority or of religious importance, such as police officers and priests. Headdresses may also be worn because of geographic location and condition. The Plains Cree wore winter hats made of buffalo and coyote hides in cold weather; however, they also wore a variety of ceremonial headdresses such as eagle feather bonnets and buffalo horn caps. Only those possessing magical powers were allowed to wear these headdresses during pursuit of a vision. Hats worn by the Naga tribes were mainly composed of boars' tusks, fur, horn, and feathers. These represent qualities such as courage, merit, and other values important to the Naga tribes.

Tattoos

Tattooing involves the piercing of the skin using needles or other sharp objects to create a specific image on the body. Tattooing, as well as cicatrization, is often practiced in order to permanently mark the body as a form of association with a particular society or with characteristics the individual possesses. It is also suggested that indigenous or tribal motives for tattooing involve connection with the Divine, sacrifice, or a form of permanent good fortune and health.

The Māori and the Native Americans have used many painful techniques during puberty rites and rituals expressing manhood. Among the Māori of New Zealand, tattooing—called *moko*—is widely practiced. Cuts one-eighth of an inch deep are made into the flesh with a mallet and a sharp blade or chisel. This procedure is very painful, but the individual is regarded as strong and brave and is highly respected. In the British Isles, ancient tribes used to tattoo their bodies in order to scare their enemies. The Romans adopted this idea and implemented it in their society by tattooing convicted criminals and slaves; the tattoos represented a low social status. A few early Christians tattooed symbols of the cross onto their bodies, but tattooing was forbidden once Christianity was declared the official religion of Rome. Once they reach puberty, Ba Thonga women are tattooed on the shoulders and stomach to represent fertility and eligibility for marriage. The Japanese introduced the use of colors in tattoos to Europe and America.

Body Piercing and Augmentation

Body piercing and body augmentation are other forms of personal ornamentation. The Marshallese pierce the earlobes with shark teeth to create holes that are gradually enlarged by inserting leaves. The enlarged earlobes may then be used to carry items such as tobacco sticks or clay pipes. Some tribes use lip plates and lip wedges that are inserted into the lip by a precision cut. The lips conform to the shape of the implanted objects as the flesh heals. The Lobi women in Ghana and the Ivory Coast, as well as the Kirdi of Cameroon, believe that evil spirits are unable to enter through the mouth if they wear lip plugs. At a young age, children are pierced with a thorn by their mothers. The hole is enlarged by inserting stalks of grass and finally a plug made of clay. Women from Chad and Sudan install lip plates resembling the beaks of the spoonbill and broadbill, which their culture deems sacred.

Scarification

Scarification is a technique in which cuts and incisions are made into the flesh to leave permanent scars on the body. It is believed that forms of scarification were considered to be marks of civilization. Natives from the Andamans use scarification practices on

young males and females to mark the transition from childhood to adulthood. The elder generation believes that by this painful experience, children will grow up to be strong individuals.

Cicatrization

The purpose of cicatrization is to cut wounds in the flesh that will create a decorative pattern of scar tissue. It is similar to scarification, but the scars are more severe and protruding. Cicatrization is thought to be a process in which individuals physically mark their passage through various stages of their lives. This procedure has been performed by tribes in Africa. In addition, female mummies have been found with decorative scar tissue along the stomach area, possibly for protection and to promote fertility.

Ornamentation in the World Today

Today there are numerous forms of ornamentation used all over the world as a means of personal expression. Globalization has allowed the acculturation of ornamentation to occur. Although certain aspects of an individual's life may be revealed by the type of clothing or jewelry he or she wears, most types of ornamentation are available to a vast number of individuals. Some people adorn themselves with expensive jewelry and designer clothes to express their accumulated material wealth, while others attempt to portray themselves as wealthy by purchasing inexpensive replicas of the same materials. The symbols of wealth, beauty, and power are always in transition, and there are often revivals of adorning techniques that were popular in the past. Tattoos, for example, were originally used to decorate and communicate different messages. They evolved from a technique of ornamentation that was practiced first among native tribes and later by criminals and the rougher individuals in society. Today, tattoos are accepted as a means to express an individual's uniqueness and creativity.

Modern society carries historical knowledge in its ornamentation. Traces of family history and culture are found in the way individuals decorate their houses, offices, and themselves. Using items that have been passed down from generation to generation, as well as new items, individuals define

themselves in the ways they decorate themselves and their surroundings.

ORWELL, GEORGE (1903–1950)

George Orwell's contributions to the field of anthropology are related to his opinions on individual freedom in relation to the state. Through both his writings and his many exploits, Orwell stressed the importance of each person's individuality over the threat of authority. He reached adulthood at a time when fascism and communism were both making gains against liberal democracy throughout Europe. Orwell was squarely on the side of the common person and the right to self-determination. In his books, his main characters consistently stood for intellectual freedom in the face of state authority.

George Orwell was born Eric Arthur Blair on June 25, 1903 in Motihari, India. He was the son of Richard Walmesley Blair, a British civil servant. His mother, Ida Limouzin, was a native Londoner who had moved to India to work as a schoolmistress. Richard and Ida were married on June 15, 1897, despite a 17-year age difference. Orwell's older sister, Marjorie Francis Blair, was born on April 21, 1898. Shortly after Orwell's birth, an outbreak of the plague struck their home district and Ida prevailed upon her husband to take the family back to England.

Richard Blair traveled back to India the following year to resume tending his opium fields. Ida set to raising nine-year-old Marjorie and little Eric, with the help of a series of nursemaids, in the small market town of Henley-on-Thames. During this time Eric was sick with bronchitis and confined to bed for five days. This type of illness would become too common as he was to have problems with his lungs throughout his life. In the summer of 1907, Richard returned

from India on leave. This reconciliation of Eric's parents soon produced his younger sister, Avril Norah, on April 6, 1908. Richard was back in India when his youngest daughter was born, and he spent the next four years in Bengal until his retirement in January, 1912. At the age of 55, he returned to the family home in Henley for good. Young Eric finally had a male presence in his house, but unfortunately, the elder Blair was not the loving, sentimental type.

Orwell's school years were not happy ones. He first attended St. Cyprian's school from age eight until thirteen, and then took the entrance examination to attend Eton College; however, his score was fourteenth at a school that only accepted twelve per class. He would have to wait until two dropped out, so he attended Wellington College. This school had a military focus, particularly during the Great War of 1914–1918. This atmosphere hardly suited young Eric, and at the first chance he took his spot at Eton.

After his graduation, he applied for a position with the Indian Imperial Police Force. His scores placed him seventh out of twenty-nine candidates, and when asked for his preference of station, he listed Burma.

In January, 1936 he traveled to the north of England to study and write on the lives of coal miners. His experiences there culminated in the novel *The Road to Wigan Pier*. He spent three months among the poor, dirty men and their families. He lived in their smelly, beetle-infested homes, sharing a small bedroom with three other men. He attended meetings of communists and followers of Oswald Mosley. Orwell was distraught to see the high level of support both these groups could muster in the region. He felt that during the 1930s, England and the other democracies of Europe were asleep at the wheel.

It was during the summer of 1936 that Orwell found his opportunity to put all of his socialist-leaning fervor into concrete action. In Spain, a civil war had begun as a result of an army-led coup against the left-wing government. Adolf Hitler of Nazi Germany sided with the rebels, organizing the return of General Francisco Franco and his Moroccan Army of Africa to aid in the fight against the socialists. Before long, a stalemate developed between the Fascists aligned with Franco and Hitler, and the leftist Republicans, supported by the Communists including Soviet Russia.

Orwell went to Barcelona and spent roughly a year there, fighting as a militiaman aligned with the Communists, but not as a member of their army.

Orwell was wounded by a shot through the neck, the bullet nearly hitting his carotid artery. After a short recovery in a field hospital, he decided there was nothing more he could do to help the Republican cause while he was in Spain. His experiences there ranged from periods of trench warfare to being targeted by the Communists who saw him as a potential “Trotskyite” and therefore an enemy of the cause. Orwell’s novel *Homage to Catalonia* is his memoir of not only his experiences there but also his declaration of undying loyalty to the socialist cause over totalitarianism, whether it leans to the left or to the right. The bitter rivalry between the Stalinist Communists and the leftist socialists led to actual jailing, torture, and murders of the other by each group. The loss of a good friend under these circumstances pushed Orwell permanently into the socialist camp. Going forward, he would not sympathize with the Communists under any conditions, not even during the Second World War.

At this time, Orwell continued to have the chronic lung problems that would prove to be his ultimate downfall. Despite this, and perhaps because of it, he continued to be quite a prolific author. He began to write pieces for the BBC, review many novels, submit essays related to the war, and keep up his wartime diary.

In 1945, Orwell completed *Animal Farm*, thought by many to be his finest work. In it, barnyard animals are increasingly exploited and disenfranchised after their revolution against their human master succeeds on a small farm. The main character, Napoleon (a pig), symbolizes Joseph Stalin and the rulers of the Soviet Union. The classic slogan, “all animals are equal, but some animals are more equal than others” describes how the totalitarian leaders justify their positions in the farm’s leadership. The elite should not be expected to do any work; their intelligence is too valuable to the well-being of the farm. The book succeeded, in part, because Orwell used a barnyard fable and animal characters to describe a contemporary, vital issue: the battle between freedom and self-determination against the all-powerful, undemocratic state. As Napoleon and the ruling pigs continue to exploit the other stronger, less intelligent animals in order to run the farm, the leaders also change the history of the revolution itself. Events that all the animals have witnessed are later declared to have never happened. The fact that no animal even challenges the rewriting of facts is clearly the warning

that Orwell has for us citizens. The citizens of all nations must be on guard against this kind of revisionist history.

In many people’s opinion however, Orwell’s greatest contribution was his last novel, *Nineteen Eighty-Four*. It is a terrifying, futuristic novel describing life under total state control. Each individual’s actions, language, and even thoughts are scrutinized by all-knowing Big Brother—the state. Omnipresent telescreens view each person’s every moment, other citizens may denounce one another for alleged violations, and the Thought Police are at every corner. The world is ruled by three large nation-states. The country of Oceania is in a perpetual state of war with either Eurasia or Eastasia. The enemy is sometimes one or the other, making it necessary to eliminate or justify the current state of alliances depending on the proper enemy. The story’s main character, Winston Smith—*Smith* as in *Everyman*—labors in the Ministry of Truth, literally rewriting history.

As far as predicting conditions in the year 1984, Orwell was quite accurate in his description of life in Eastern Europe and the Soviet Union (Eurasia in the novel). China also (similar to Eastasia in the novel) was under a totalitarian system. Citizens of those nations were spied on by secret police and could not freely criticize government policies or expect an improved standard of living. Consumer goods were of poor quality, in short supply, and travel was severely restricted. In Orwell’s native Britain (Oceania in the novel), however, the political reality was still one rooted in parliamentary democracy.

But Orwell was not attempting to *predict* what the political future would be in *Nineteen Eighty-Four*; he was *warning against* a potential political future. Orwell challenged us as a democratic citizenry and he implored us to ward off the loss of individual liberty at the expense of government control.

By the time *Nineteen Eighty-Four* was published, Orwell was a very sick man. Hospitalized in the fall of 1949, he was to suffer for months until the end. He died on January 21, 1950 at the age of 46 of complications from tuberculosis. Orwell had lived a short but full life. He had traveled extensively, been a soldier, been married twice, and lived his convictions throughout it all.

OSTEOLOGY, HUMAN

Osteology is the subdivision of anatomy pertaining to the study of bones of vertebrate animals, including humans. It comprises the names of specific bones of the skeleton, their placement and articulations in relationship to other bones, body proportions, and visible and microscopic features of osseous tissue. Among Greco-Roman anatomists, who followed the Hippocratic proposition that body proportions of the trunk and upper and lower extremities were related to various illnesses, the term *skeleton* meant a dried body (mummy) as well as the bony framework of a cadaver or a defleshed specimen.

Painters and sculptors of the Renaissance were interested in size and shape relationships of the living body and skeleton, and by the 17th century, systems of measurement using calibrated instruments were invented for scientific and medical purposes. Osteology continues to play a critical role in medicine, as in the fitting of prostheses to severed limbs, and in sports medicine, where size and shape variables of athletes' bodies may be indicative of success in particular sporting activities. Osteology is relevant to engineering, space travel, architecture, and anthropological investigations of prehistoric and modern human skeletons.

Systems for measuring and describing morphological features of the human skull, dentition,

and postcranial bones of skeletal, cadaveral, and living subjects constitute the methodology of *anthropometry*. Standards for taking measurements and classifying size and shape variables evolved in the mid-17th century in Europe, along with measuring instruments. A century later, "schools of anthropometry" were established in France by Paul Broca (1824–1880) and his successors Leonce-Pierre Manouvrier (1850–1927), Paul Topinard (1830–1911), Theodore Hamy (1842–1908), and Armand de Quatrefages (1810–1892); in Germany by Rudolf Virchow (1821–1902) and Rudolf Martin (1864–1925); in England by Karl Pearson (1857–1956) and Geoffrey M. Morant (1899–1964). In the United States, Ales Hrdlicka (1869–1943) of the Smithsonian Institution introduced methodologies of the French school, but Earnest A. Hooton (1887–1954) of Harvard University taught the anthropometric standards he had learned from Robert R. Marret (1866–1943) and Arthur Keith (1866–1955) while studying in England. The professions of these investigators of osteological diversity were in anatomy, medicine and pathology, anthropology, and biometrics. Their research goals were human racial classification, phylogeny based upon studies of assumed relationships between fossil hominid specimens and living populations, biological affinities of humans to other primates, and more recently, an expansion into questions about growth and development, health and nutrition, genetics, and applications of osteology and

anthropometry to human identification in medical-legal contexts (forensic anthropology).

Osteology in its anthropometric context acquired a unique nomenclature: *craniology* and *cephalometry* with respect to cranial studies of skeletal and cadaveral and living subjects, respectively; *osteometry* and *somatometry* of postcranial bones; *cranioscopy* and *anthroposcopy* with respect to morphological (non-metric) observations; *somatotypology*, which focuses on ranges and classification of body forms of cadavers and living subjects. These terms are not widely used today, but *osteology* and *anthropometry* remain in scientific parlance.

Among the multiple applications of osteological data in the biological sciences is a developing interest in bone tissue remodeling in response to muscular-skeletal stress. *Markers of occupational stress* (MOS) or *musculoskeletal stress markers* (MSM) may be observed in a skeleton in cases where a habitual activity has resulted in the formation of lesions at loci of muscle and ligament attachments. For example, hypertrophy of the supinator crest on the proximal end of an ulna may result from repeated supination and hyperextension movements of the forearm, as in spear-throwing and baseball pitching. Although a specific lesion may be the consequence of several behavioral activities, their recognition, particularly in the presence of an archaeological record containing weaponry, tools for food preparation, or evidence of strenuous boat paddling, may shed light on lifeways of extinct populations whose remains have been preserved for osteological analysis. Other current osteological studies conducted by biological anthropologists include examination of fossil and living primate postcranial bones in order to better understand the evolutionary course of patterns of locomotion, including the origins of bipedality, effects of stress experiments on volunteer subjects in order to estimate osseous modifications, and bone scanning to acquire fuller knowledge of microstructures and developmental changes. Thus osteology provides data about our evolutionary history, adaptability to changing and different ecological settings, and medical-legal issues.

PACIFIC RIM

The Pacific Rim is an area that encompasses those land masses surrounding and within the Pacific Ocean. The Pacific Rim as a region is significant due to its high levels of volcanism and tectonic activity. The boundaries are often referred to as the “Ring of Fire” because it is home to the world’s foremost belt of volcanic activity, comprising over 75% of the world’s active and dormant volcanoes. The Ring of Fire arc stretches from New Zealand to the eastern edge of Asia and then north across the Aleutian Islands of Alaska and south along the coasts of North and South America. The Ring of Fire is situated at the juncture of the Pacific and the Antarctic, Nazca, Cocos, North American, Eurasian, and Indo-Australian tectonic plates.

As the Pacific Plate moves northwestward, colliding with and sliding underneath other plates (known as subduction), rock is melted into magma and rises to the surface as lava, forming volcanoes over “hot spots.” Island chains are a result of the plate passing over these hot spots leading to volcanic eruptions. Linear island archipelagoes such as Hawaii are characterized by volcanism, earthquakes, and deep ocean trenches surrounding the islands.

All of Earth’s tectonic plates are in flux; when they move, intense geologic activity occurs along the edges. Several things can happen as a result. For example, when the plates move away from each other, magma from the earth’s core will rise up to form a new seafloor and may eventually break through the ocean’s surface to form an island. Alternately, when the plates move toward each other, they will either slide past each other, or subduction will occur.

If parts of a plate boundary slide past one another in opposite directions (for example, the San Andreas

Fault), minor earthquakes can occur. The faults also may create cliffs thousands of feet high on the ocean bed. When two plates collide and one is forced under the other, deep into the Earth’s interior, the subsumed plate encounters high temperatures and pressures that partially melt solid rock. Some of this newly formed magma rises to the Earth’s surface and erupts, forming chains of violent volcanoes like the Ring of Fire. These narrow plate-boundary sites, known as subduction zones, are also associated with the formation of deep ocean trenches and big earthquakes. When there is an earthquake under the sea, one side of the ocean floor suddenly drops downward, beneath the top edge of the subducting plate. The resulting vertical fault will generate a tsunami with often devastating consequences.

The movement of the Indo-Pacific Plate under the Pacific Plate has created volcanoes in New Guinea and Micronesia. The resulting volcanism has created a myriad of different island types. High volcanic islands such as the island volcano of Krakatau (“Krakatoa”) in Indonesia, which erupted on August 26, 1883, created a series of huge tsunamis, some of which reached heights of 40 meters and killed more than 36,000 people on the islands of Java and Sumatra.

The Ring of Fire—and hence the Pacific Rim—are important not only because of the natural catastrophes which can result, but for the impact they have had—and still have—on human populations. The formation of new land masses in the ocean greatly influenced the movement of prehistoric peoples across the seas, led to the development of hundreds of unique cultures in partially or totally isolated environments, and helped us to understand how people adapted to insular environments.

PACIFIC SEAFARING

Few subjects captured the imagination of early European explorers more than the seafaring exploits of Pacific islanders. In 1768, the French explorer, Bougainville, dubbed Samoa “The Navigators’ Islands,” and the British captain, James Cook, noted that Polynesian canoes were often as fast and maneuverable as his ships. Subsequent commentators, particularly within the anthropological community, have retained their predecessors’ fascination.

Western views of oceanic seafaring abilities have shifted several times. Through the mid-20th century,

indigenous traditions of voyaging, exploration, migration, and settlement were taken quite literally. In 1957, Andrew Sharp argued that, unless aided by instruments, human beings couldn’t navigate successfully over long distances. Therefore, colonization of new islands was almost certainly the result of accidental drift voyages by sailors blown off course or forced, against their will, out to sea.

Sharp’s conclusions were challenged by the pioneering ethnographic work of Thomas Gladwin (1970) on Puluwat in Micronesia and David Lewis’s more wide-ranging survey. They and others have documented voyages of hundreds of miles with accuracy comparable to that of Western mariners aided by modern instruments, and they carefully described indigenous navigational techniques.

A second line of evidence casting doubt on Sharp’s drift voyage argument is provided by the direction of settlement: from west to east, against the prevailing winds. Computer simulations comparing winds and currents with the geographical and cultural relationships of various islands and archipelagoes have demonstrated that oceanic exploration and settlement could not have been a result of accidental drift, but must have eventuated primarily from purposeful voyaging by skilled navigators.

The final line of evidence supporting the proficiency of oceanic navigators comes from experimental voyages with replicas of traditional canoes, using traditional navigational techniques. *Hōkūle’a*, a performance-accurate

replica of a Hawaiian double-hulled voyaging canoe, built with modern materials but to traditional design, was sailed successfully through almost all of Polynesia. In the aftermath of *Hōkūle’a*’s success, other voyaging canoes were built in the Cook Islands of Aotearoa (New Zealand), and elsewhere in Polynesia. In 1993, the Hawaiian Voyaging Society launched *Hawai’iloa*, a voyaging canoe constructed out of natural materials. *Hawai’iloa*, like its predecessors, has now logged thousands of miles of deep-sea inter-island travel. Meanwhile, many indigenous

communities are working to revive their seafaring heritage. Noteworthy in this regard are the efforts of the Vaka Taumako Project in the eastern Solomon Islands.

Canoe Design

Most commonly, Pacific mariners used single-outrigger canoes ranging from small vessels paddled by one or two men (or occasionally women) for coastal travel and inshore fishing to vessels that might approach 100 feet in length and rival European sailing ships for speed. In Micronesia, parts of Melanesia, and most Polynesian outliers, canoes are designed with an interchangeable bow and stern. The vessel is tacked (i.e., has its course changed) by moving the sail from one end to the other, thereby always keeping the outrigger upwind. In most of Polynesia, bow and stern are distinct; the outrigger is always kept to the same side (most often, to port, i.e., the left side of the ship); and the canoe is sometimes sailed with the outrigger in the craft's lee (sheltered side).

The most imposing of Pacific voyaging canoes were the great double-hulled vessels of the Polynesian heartland. Such canoes have been reported from Aotearoa and Tonga to Rotuma, Tuvalu, and north to Hawai'i. Voyaging canoes could cover more than 100 miles per day with a favorable wind. The outrigger or double-hull design provides resistance to leeway drift without the need for a deep keel, which is a hazard when sailing among shallow reefs. More specialized developments included the New Zealand Māori's impressive single-hulled, outrigger-less canoes. For an inventory of Pacific Islanders' canoe construction and design, Haddon and Hornell's encyclopedic treatment remains unparalleled.

Navigation

Most Pacific navigators rely mainly on the movements of celestial bodies. Ideally, the navigator identifies a star that rises directly over his target island and points the canoe's bow toward that star. When the first star rises too high, he turns his attention to another following approximately the same trajectory. If a sequence of stars does not rise or set directly over the target island, the navigator sets off the bow at an appropriate angle while compensating for wind and current.

Most problematic is detecting currents on the open sea. A capable navigator knows the prevailing

currents. He confirms their direction and speed while near the point of embarkation or when sailing over shallow reefs. Some navigators assert that by feeling wind velocity and seeing or feeling the condition of the sea, they can even discern a current's direction in deep water, far from land.

The navigator may gauge latitude by identifying zenith stars or by observing the altitude at which specific stars rise and set. Longitude must be estimated by dead reckoning—the navigator fixes the canoe's position by estimating the vessel's speed, direction, and how long it has been at sea. Since he must keep a running total of the vessel's progress at all times, he cannot sleep, other than occasional brief naps, even on a lengthy journey.

When stars are not visible, the navigator relies upon prevailing wind and wave patterns. In addition, long-distance voyagers may have employed "latitude sailing"—sailing to the latitude of the target island but well to windward, then making landfall by running downwind. They minimized their risk by island hopping, thereby breaking lengthy journeys into shorter segments. Wherever possible, they aimed for groups of islands rather than isolated targets.

Navigators usually attempt to make landfall during daylight. Before land is visible, its presence may be indicated by birds that roost on shore but feed at sea during the day. Reflected waves are shaped differently from waves produced directly by the wind and can, at times, be felt at distances of more than twenty miles from land. Clouds tend to accumulate around the peaks of high islands, indicating their presence; and a greenish tint to clouds may reveal the presence of an atoll that cannot be seen from a canoe.

PALEOANTHROPOLOGY

Paleoanthropology is a multidisciplinary approach to exploring the evidence for the evolution of humans and their fossil ancestors. Paleoanthropology explores human anatomical structure, archaeological remains, habitat, and chronology through the diverse disciplines of biological anthropology, primatology, archaeology, ecology, geology, paleontology, biology, genetics, and cultural anthropology. In exploring the question of human evolution, paleoanthropologists link ideas through evolutionary theory, comparative anatomy, environmental and cultural influences on behavior, and geological time.

History of Paleoanthropology

In the 1860s, only a few pre-modern fossils had been found; scientists did not agree upon their identification or age, let alone upon the model to explain human evolution. Charles Darwin had just published *On the Origin of Species* in 1859 on natural selection as a mechanism to explain evolutionary change through time. Few people yet realized the extent of the antiquity of humanity.

On the European continent, most people subscribed to the school of Catastrophism, led by the writings of French paleontologist Georges Cuvier. According to Cuvier, fossils found in different geological strata illustrated successive revolutions, during which all living things were destroyed and replaced by new forms. Cuvier and his supporters were unwilling to accept early ideas of evolution, and did not believe in the existence of human fossils. In Britain, the prevalent school of thought was Uniformitarianism, led by James Hutton and Charles Lyell. Uniformitarianism held that natural processes observable today were responsible for the gradual modification of the

earth. Proponents of this view believed that the earth was at least several millions of years old. The Uniformitarian position set the stage for the relatively quick acceptance of Darwin's work and the theory of evolution as a whole.

The idea that humans had evolved from an ape-like creature was not problematic for proponents of Uniformitarianism. Many perceived a gradual evolution of humans from a form of anthropoid ape. As more fossil hominid forms were unearthed, such as the Spy Neandertals from Belgium, people began to search for the "missing link" between apes and humans. Ernst Haeckel suggested that there should have been a completely transitional form between apes and humans, one that was neither ape nor human. Paleoanthropologists of the mid- to late-19th century focused primarily on description and typology, organizing fossils into successive evolutionary stages and racial categories. This temporal and typological sorting of fossils (and living people) did little to explain why and how humans evolved in the patterns they did.

In the 1930s a movement began to form a synthetic theory of evolution, combining genetics, evolutionary theory, and populational studies into a single perspective, known subsequently as "The Modern Synthesis." It rejected the descriptive, typological emphasis commonly practiced in zoology and physical anthropology up until that point. By the early 1950s, this major paradigm shift had a most profound effect on American biological anthropologists. Researchers began to focus on ecological change and cultural behavior as factors in human evolution. Today, paleoanthropology as a research focus spans a broad range of topics and disciplines.

The Paleoanthropological Approach

Paleoanthropology differs from paleontology in that it primarily studies human origins; because of this, the application of some of the standard tools used by paleontologists can be problematic. Early fossil humans, like other animals, were subject to evolutionary forces such as natural selection, and had to adapt biologically and behaviorally to specific environments or ecological niches. When fossil humans began to rely on cultural adaptations to assist them in survival, biocultural feedback created a cultural buffer between hominids and their environment. Because of this, there is considerable debate over what types and levels of selective forces can be used to

predict fossil human lifeways. Dietary habits, advanced cognitive abilities, communication and language skills, and technological sophistication all played a role in shaping human adaptation to the environment, making the concept of the ecological niche, and even natural selection, less useful as a research tool.

Paleoanthropology in the Field

Like most fossils, human fossils are rare and difficult to find. As a result, fieldwork is an important part of paleoanthropology. Early fieldwork, such as that conducted by Robert Broom or Louis and Mary Leakey, was a small-scale effort by one or two individuals and their hired crew. These individuals were experts in some areas, such as excavation or anatomy, and called in experts on key questions such as fossil species identification or interpretation.

Today, while one individual still leads a field project, there has been a shift in focus toward a team approach. This interdisciplinary approach, first championed by F. Clark Howell, encourages collaboration among an international team of specialists, representing many fields of study.

Biological anthropologists examine fossils for anatomical features of hominids using their knowledge of comparative primate anatomy and biomechanics. Geologists help to locate potential human occupation sites by examining maps, aerial and satellite photography, and the stratigraphy of a region. They also help to develop a dating sequence for the region. Paleontologists estimate the age of the site through a comparison of fossil animals, or fauna, in other nearby sites. Reconstructing past environments, or paleoenvironments, involves cooperation from paleontology as well as ecology, paleobotany, palynology (fossil pollen grains), and geomorphology (water, land features). Archaeologists recover material cultural remains from human behavior and can provide dates for the site based on features of the artifact's style, location, and raw material.

Paleoanthropology in the Lab

While fossil recovery and description are important (without which there would be no fossils to study), equally important are the research questions these fossils can help answer. Like all fields of science, paleoanthropology relies upon the scientific method of

Source: © Robert Jurmain.

inquiry, hypothesis formation and testing. Through the collaboration of researchers from many fields, paleoanthropologists examine the broader picture of human origins through developing competing phylogenies, or evolutionary trees, which reconstruct possible relationships between fossil species. These phylogenies are tested against the fossil record and refined with new discoveries or interpretations. Among the key research questions asked by paleoanthropologists are:

- How, when, and where did modern humans evolve?
- When did bipedalism evolve, and why?
- When and why did tool-making develop, and who were the first toolmakers?
- What is the ancestor of the genus *Homo*?
- How many fossil species of hominids existed?
- How did the modern human brain evolve, and why?
- How did the human capacity for language evolve, and why?
- How and when did modern humans become so diverse?

These questions, approached using many lines of evidence and fields of study, guide our understanding of human origins and our unique adaptations.

PALEOECOLOGY

Paleoecology is both a field of ecology concentrated on the study of the ecology of fossil organisms and a branch of cultural and environmental anthropology aimed at the detection of the mutual influence and interdependence of prehistoric culture (or society) and its natural environment.

The formation of paleoecology as special field of knowledge coincided with the middle of the 20th century, and was the crucial time for the initial comprehension that human livelihood systems' diversity is directly connected with the features of the natural geographic environment. As a result, the analysis of the geographic components of certain ambient adjoining areas inhabited by separate groups of population has become a subject of principal importance. From the early 1960s the process of the creation of a database necessary for cataloging prehistoric fauna, flora, relief, and any climate reconstruction has been significantly intensified.

As a result one can trace the formation of new direction in the field of archaeological investigation—environmental archaeology, which developed mainly in the context of European Stone Age archaeology. From the very beginning its primary goal has been postulated as an interdisciplinary analysis of the geographic environment inhabited by Prehistoric populations. Since the late 1970s two fundamental approaches could be distinguished in its frameworks,

and gradually each of them has become an independent discipline. The first one—geoarchaeology—concentrates its attention predominantly on the natural geographic context of archaeological objects. Methods of geology, geomorphology, and climatology are used in conjunction by the highly skilled geoarchaeologists in order to reconstruct the circumstances that have had local influence on archaeological sites, that have led to the formation of cultural remnants, and also to reconstruct the further history of their fossilization. In recent years artifact and site conservation, preservation of the same from natural ruination, technical analysis of artifacts and their raw material source base, artifact absolute dating, and other issues have also become the part of the scientific concerns of the representatives of this discipline. The other group of environmental archaeologists concentrates their attention on ecological links between human society and natural environment.

In the former Soviet Union the prehistory of the ecological context of separate settlements became the subject of intentional investigation during the late 1960s and early 1970s. Since that time representatives of a broad spectrum of natural sciences have taken part in numerous archaeological excavations, and the results of their activity have enabled them to reconstruct in concrete the natural geographic environment inhabited by a certain group of hunter-gatherers. The first attempt by Soviet archaeologists to theoretically generalize the results of such interdisciplinary excavations was made by S. Bibikov. In 1969 he proposed the method of paleoeconomic simulation, the frameworks of which call for the specificity of the material culture and household activities of the concrete settlements' inhabitants, on the one hand, and the features of their natural environment, on the other, to be taken into account. During the 1970s to 1980s, he and his many apprentices explored this method in many prehistoric settlement case studies. As a result, it was established that natural environment had significantly influenced the formation and development of separate groups of the populations and their culture, and, in its turn, was subjected to many essential changes caused by these human collectives' activities. Based on this conclusion Bibikov elaborated his concept of paleoecological and paleoeconomic crisis, which is regarded as an objective theory and a natural result of prehistoric populations' advances and activities taking place in a permanently changing environment. It also becomes possible to distinguish several

stages of such crisis development during 9000–6000 B.C., development which is correlated with phases of geographic ambient evolution as well as with changes of the “livelihood activities” of hunter-gatherers. As a result, a new specific direction of archaeological and historical investigation—an ecological one—was founded. Its purpose is often regarded as the detection and analysis of connections that exist between a specific cultural object and its natural environment.

Representatives of Western-European environmental archaeology and experts in the ecological approach in Soviet archaeology and prehistory are taking rather close paths in looking to a prehistoric population's culture and specific features of its mode of life for explanation. Questions of the hunter-gatherers' mobility as well as their livelihood activity in certain localities are at the center of attention of practitioners of both approaches. At the same time, there is also a clear difference in their initial idealized theoretical postulates. So, in contrast to the Western-European and American environmentalists, the majority of the Soviet researchers believe that the social sphere of the prehistoric culture levels an environmental impact on material culture that can already be seen at the earliest phases of human history.

Practitioners of the paleoecological approach in both Soviet and Western archaeology see their main task in interpretation of any results of concrete site investigation as taking into account the site's natural ambient dynamics. In order to realize this goal, they try to avoid broad generalizations or the creation of a simplified or complicated simulation of nature-society relationships, so they prefer a simple explanation. Of late it was proposed to distinguish local paleoecology, which concentrates its attention on problems of residence, place, and visiting a territory's ecological situation reconstruction, from regional paleoecology, the object of which is to study features of the settlement system as well as a regional source base evaluation. Conversely, an original simulation of historical processes that took place on the territory of what is contemporary Ukraine during the Mesolithic times illustratively proves the high cognitive potential of the use of this approach in wider spatial frameworks.

Today the ecological approach is gradually improving not only in Stone Age archaeology but also in many adjacent fields of knowledge that are concerned with the investigation of prehistoric societies. First it happened with cultural and social anthropology,

ethnology, paleodemography, paleosociology, paleogeography, as well as with other sciences and humanities. In particular, since the 1970s it has been repeatedly stressed that in prehistoric times the main stages of natural geographic environment changes correlate well with human morphology evolution as well as with the society's material culture and livelihood systems development. The main role in this process, as a rule, was given not so much to the living conditions of a prehistoric population as to their dynamics in time.

Recent decades have brought new insight to the theoretical background of paleoecological studies. Today the concept of the influences of cultural adaptation, stresses, resilience, and adjustment of a society are an integral part of paleoecology along with the application of theories of sustainability, socio-economic metabolism, co-evolution, and nature colonization.

PALEOMAGNETISM

Paleomagnetism is both the fixed orientation of a rock's crystals based on the orientation and direction of the Earth's magnetic field at the time of the rock's formation and the study of such phenomena used as indicators of Earth's paleomagnetic history.

The Earth's magnetic field orientation as a dipole is not fixed and is continuously changing by small

increments. This leads to an effect known as polar wander. This continuing process is still active today and forces charts of the earth's magnetic field, known as isomagnetic maps, to be redrawn every 5 years.

The phenomenon of polar wander has been used extensively in geology as an indicator of global position and the geologic age of iron-bearing rocks known as ferromagnetic rocks. Studying paleomagnetism has, in part, established the position and intensity of the Earth's magnetic pole over geologic time. Geologists use this new sagaciousness to determine aspects of global tectonic history. Using paleomagnetic techniques it now becomes possible to determine the past relative positions of two separate continents, provided they were previously conjoined to the same plate. A paleogeographical reconstruction of the earth can then coalesce from global paleomagnetic data endowing geologists with valuable insight into Earth's past.

The ability of geologists to determine past magnetic fields is locked in the chemistry of ferromagnetic rocks. These substances have more electrons spinning in one direction than the other; thus the individual magnetic fields of the atoms in a given region tend to align in the same direction. When an igneous rock is crystallized from lava or magma in the presence of a magnetic field, the magnetic elements leave a magnetic signature frozen in the rock. During the cooling of molten rock, iron-bearing minerals become magnetized in alignment with earth's magnetic field as they descend through a critical temperature known as the Curie Temperature, which occurs at approximately 500°C–600°C. The rock's magnetic properties are retained (thermal remanent magnetism) for geologically long periods unless the rock is again heated to near the Curie temperature. Rock samples have their thermal remanent magnetism determined by magnetometers in a laboratory. Around the world, thousands of formations and outcrops have been paleomagnetically analyzed and documented making accurate paleocontinental maps of Earth a reality and furthermore giving geologists an almost clairvoyant gaze into the past.

Dramatic alterations to the polarity of the Earth's magnetic field were first noticed on the seafloor of the Atlantic Ocean. Known as the mid-Atlantic spreading ridge, this narrow rift continuously deposits new basalt separating the east coast of North America from the west coast of Europe and Northern Africa. The seafloor in the Atlantic is striped with bands of

rocks magnetically trending northward and alternating parallel bands trending southward. Presuming the seafloor at the Mid-Atlantic rift spread similarly in the past as it does today, then as time progressed, the Earth's magnetic field regularly underwent a full reversal in dominant direction. Thus, magnetically, the seafloor in the Atlantic appears as linear anomalous bands. These reversals were recorded in the basalt going back approximately 100 million years. In that time, the rates of reversal have varied considerably from one reversal to the next. These magnetic reversals are recorded not only in basalt, but also in other igneous rocks and sediments. If the reversals themselves represent simultaneous cosmopolitan phenomenon, they then act as unique stratigraphic markers wherever and whenever they occur. These polarity events, therefore, provide a precise tool for chronostratigraphic correlation of marine and terrestrial sediments. Based on seafloor spreading and sediment depositional rates, the reversal process is thought to occur over a period of 1,000 to 10,000 years which includes a 60% to 80% decrease in intensity of the field some 10,000 years preceding the reversal, whereas the actual reversal itself only takes 1,000 to 2,000 years. The field then builds up in intensity returning to normal intensity. The last polar reversal occurred approximately 700,000 years ago. Polar reversals have various durations and are divided into two main groups: chrons (epochs) occur when the polarity is the same for a long period of time, and subchrons (events) occur when the polarity only maintains a single direction for a relatively short period of time.

The use of paleomagnetism as a global chronometer has been extended in many other sciences. In archeology, the pottery and bricks of ancient peoples are aged using carbon 14 dating showing the date of their last cooling. These samples can also give a relative position of the magnetic pole at that time. This has allowed archeomagnetic investigations to reconstruct the recent course of the magnetic pole. The ability to define boundaries between time periods makes paleomagnetism very appealing. Two outstanding examples are the Peking-man site of Zhoukoudian in northern China, and the Trinchera Dolina site, in Atapuerca, Spain. These sites are now considered the oldest unequivocal human occupation sites in Europe thanks to paleomagnetic studies. Neither Zhoukoudian nor the Trinchera Dolina provided material sufficient for isotopic age determination; however, Zhoukoudian

paleomagnetic determinations from fine-grain sediment fill have allowed the Brunhes/Matuyama boundary to be isolated at a level beneath the sediment containing the earliest Peking man fossils. Paleomagnetic analysis of the Trincheria Dolina has placed the Brunhes/Matuyama boundary in sediments that were deposited after any sediments with included artifacts and human fossils. These remains were, therefore, estimated to be approximately 800,000 years old. Nowhere else in Europe have fossils been found that demonstrate human occupation or arrival before 500,000 to 600,000 years ago, implying that only the Trincheria Dolina people were present before then.

The properties of the earth's magnetic field offer scientists inexhaustible opportunities to explore the inner complexities of the earth and the activities of its more recent inhabitants. Using the reversal punctuations decoded from the rocks and sediments of long ago and correlating these to geological and paleontological insights, new and enlightening aspects of ancient and modern history are being brought to life as well as new means to measure that history. Understanding geomagnetism and how it has affected the life history of the earth is in the forefront of geologic research and will continue to be paramount in this discipline.

PALEONTOLOGY

Paleontology is the study of prehistoric plant and animal life. It is made possible by fossils: the remains and traces of once-living organisms that have become

preserved in rock. Fossils enable paleontology to not only measure the shapes and diversity of past life but also to determine the nature of ancient environments, reconstruct paleoecologies, and observe the patterns of evolutionary change. To achieve this, paleontology integrates extensively with other earth, biological, and physical sciences, and more recently with mathematics, planetology, and climatology. Paleontological research has made significant contributions to understanding geological and biological processes, such as global tectonics and organic evolution. Important for human nature, this has enabled us to observe our own evolutionary heritage and relationships with other species through the fossil record. Amid growing concern for the natural health of earth, paleontologists provide valuable data for the study of climate change and extinctions.

Most organic remains and traces of plants and animals have a common fate: to be decomposed and broken down to rejoin the earth from which they originated. But this process is not perfect, and, under certain conditions, the remains and traces of life become trapped and incorporated into rock, becoming preserved for up to billions of years. These remnants are known as fossils, and they are the primary objects of study in paleontology, a word derived from the Greek, meaning “study of ancient life.”

Human beings have long been curious about and attracted to the fossil remains of plants and animals, as evidenced by artifacts of fossilized tree resin, shells, and wood found in camps dating back tens of thousands of years. This valuation of fossils as simply objects that are visually appealing would continue for some time. Even during the birth and development of geology as a science, humankind interpreted fossils essentially as strange-looking stones and considered them to be similar in origin to minerals, crystals, and other rocks. The realization that fossils were once living organisms was a profound development that shifted some emphasis away from geological theory and toward a more biological approach.

Fossils are not restricted to the bones of vertebrates. They also may form from the body parts of invertebrates, plants, and microscopic life, collectively called *body fossils*. In addition, the footprints, burrows, borings, and other relics of the behavior of an organism during its lifetime may become fossilized and are known as *trace* or *ichnofossils*. A challenge of paleontology is to deal with the incompleteness of the fossil record due to our planet's limited environments being

able to maintain the conditions suitable to bury and fossilize an organism's remains over time. Not all organisms have the same potential for preservation. The process of fossilization can be arduous, and organisms with hard body parts and robust traces will be preferentially preserved over soft-bodied organisms. These factors mean that not all organisms will leave a fossil record, and, in fact, fossilization is exceptionally rare for any life form. There will be considerable gaps between forms. The lack of abundant fossils in the space between ancestral and descendant species was one of the strongest arguments railed against Charles Darwin's theory of organic evolution. But even the incomplete fossil record provides abundant data at significant points of life's history to answer specific paleontological questions and test evolutionary theories.

By recording life over cycles of geologic time, fossils have captured evidence of many useful concepts such as extinction, organic evolution, and continental drift. We may make interpretations of the nature of ancient environments because a series of environmental parameters such as light, temperature, salinity, and other factors that affect ecological tolerance controlled the distribution, diversity, and abundance of fossil organisms. Such paleoenvironmental analysis allows us to make useful comparisons with today's changes in environment and their impacts on biological diversity.

Other applications of paleontology include determining the relative age of rocks and correlating geological formations via biostratigraphy. This has been of immense benefit in mapping and understanding geology, in guiding the search for economic mineral deposits, and in better understanding the role of fossil life in the genesis of certain ores. In a similar vein, the distribution of fossils contributes much to the discipline of biogeography, showing the pattern of dispersal of organisms with time. As we have developed new techniques in molecular biology and DNA technology, paleontology provides valuable complementary data to enhance accurate conclusions about life's development.

The Fossil Record

The ultimate fate of most living organisms is to be decomposed into their composite elements and cycled back into the biosphere, where they become available for use by other living tissues. Even the traces and structures resulting from an organism's life habits are usually eroded and cycled back into the lithosphere to form new substrates. While these processes are efficient, however, they are not perfect. If some of the organic matter and traces escape this cycle by becoming trapped and consolidated into layers of rock, it may be preserved and fossilized, the evidence of past

life that is the building block of paleontology. Such processes have been operating since early in the history of earth, as illustrated in the Apex Chert of Marble Bar, Western Australia, which contains fossil microbes dating back 3.5 billion years.

The study of how ancient life is incorporated into the fossil record is called *taphonomy*, a study of literally everything that happens to an organism from the moment that it dies until it is collected for scientific study. The early stage of taphonomy occurs when an organism's dead remains are affected by various biological and environmental

Gascyone Junction Road, Australia

factors before being buried and isolated from them; we call this phase *biostratinomy*. The remains may be affected by weathering, transport, erosion, scavengers, and a host of other factors that act to alter the remains further from their life morphology. Burial then isolates the remains further from biostratinomic factors, and the remains begin their geological alteration to a fossil. We call this stage *diagenesis*, and it encompasses all of the changes to the remains, such as compression, deformation, breakage, and the geochemical process of fossilization. Body fossils such as bones, shells, and woody tissues will cause different minerals to precipitate out of groundwater solutions or other diagenetic effects to replace the organic tissue with minerals or preserve the remains as an imprint.

Fossils that can be studied with the naked eye or with low-powered magnification are called *macrofossils*; generally we call those smaller than 1 millimeter *microfossils* and their study is termed *micropaleontology*. Microfossils are a common feature of the geological record, and we can find them in most marine and terrestrial sediments. Although every kingdom of life is represented in the microfossil record, the most abundant forms are protist skeletons or cysts, together with pollen and spores from vascular plants.

Traditionally, we divide micropaleontology into three areas of study on the basis of microfossil composition: calcareous, siliceous, or organic. We call the study of organic microfossils *palynology*. Micropaleontology is a major component of biostratigraphical studies and is used heavily in petroleum geology, while there is growing use of palynology in forensic investigation for law enforcement.

Because taphonomic processes can severely modify organic remains, paleontologists must carefully consider their impact when assessing fossils and using them for meaningful conclusions. Although it is true that most aspects of taphonomy act to degrade the quality of inherent information,

we must also consider that any modifications that occur can, in themselves, be potential sources of information. For example, a fossil bone with characteristic erosions that degrade its pristine morphology at the same time indicate that it has been consumed and partly digested. Thus, the loss of morphological data during biostratinomy is the gain of paleoecological data.

Hard-bodied organisms dominate the fossil record because soft tissues are the first to suffer postmortem decay and very rarely survive the taphonomic path to fossilization. This is but one cause of natural bias in the fossil record for which paleontologists must account. Fortunately, some soft tissue does fossilize and can provide useful data of extinct life forms.

Sparked by my participation in an expedition that discovered a complete *Brachylophosaurus* dinosaur in the Cretaceous formations of eastern Montana, my own research focuses on the taphonomy and mechanisms of soft-tissue preservation. The Montana specimen has an abundance—90% of the skin and the gut contents—of preserved soft tissue so as to give the appearance of a naturally mummified animal. There are also remarkable, three-dimensional preservations of the right shoulder muscles and neck. Such rarely preserved details of form allow much more accurate reconstructions of functions. This type of preservation must require rapid in situ mineral growth in the

presence of significant microbial activity, but we have still to resolve the exact nature of the minerals and processes.

Some organisms leave traces of their existence upon an environment from their behavior rather than from their physical remains. We call this disturbance of a substrate by living organisms *bioturbation*. This occurs in any marine and terrestrial environment where organisms may cause borings, tracks, trails, burrowings, nestings, footprints, and other structures as a result of their life behavior.

Ichnofossils can be of particular value to paleontologists who seek to accurately reconstruct life's history. Because ichnofossils are formed during the organism's life rather than death, they may preserve potent information unavailable through the interpretation of body fossils. This may include evidence of ecological interactivity as illustrated at the Cretaceous age Lark Quarry in Queensland, Australia, where a substantial area of fossilized feet impressions indicates a herd of small bipedal dinosaurs changing direction and speed of motion in apparent response to the appearance of a larger carnivorous theropod. We can interpret the ichnofossil data to show a predator-prey relationship—or at least an interaction between different species—that we could only speculated on through body fossil evidence. A different example of fossilized behavior may be found in the

fossilized remains of nests, eggs, and feces (coprolites), which are classified as ichnofossils. Coprolites can provide valuable clues to paleodiets and the ecological relationship between fossil plants and animals, while nests and eggs can offer evidence of reproductive behavior.

Ichnofossils have several other advantages over body fossils. They may be far more abundant than the fossilized remains of the organisms that formed the trace, as an organism, particularly if mobile, can make many traces in its lifetime. This provides a greater likelihood that data

from the organism will be preserved into the fossil record. Ichnofossils may record the presence of organisms in strata that is otherwise devoid of fossil remains, including those with soft bodies that otherwise would not be preserved. They are also usually found in situ, providing therefore more reliable evidence of ancient communities compared to body fossils that are more easily transported or reworked. The sum of these features is a vastly more accurate fossil record with which paleontologists can work.

Ichnofossils may provide excellent data to support morphological reconstructions from fragmentary or poorly preserved body fossils. At Laetoli, a Pliocene paleoanthropological site in northern Tanzania, a remarkable track-way of *Australopithecus afarensis* footprint impressions dated to 3.6 million years in age greatly enhances our understanding of hominid morphology at that time. Other ichnofossils at the site help illustrate the ecological settings that shaped early human ancestry and contributed to the development of upright posture and bipedal locomotion in humans, nearly 1 million years before widespread tool use.

Origins and History of Paleontology

Humankind's interest in fossils dates back at least to Mid-Paleolithic times, evidenced by fossil invertebrates such as gastropods and coral found collected

together in the camp of Neandertals in southern France. Much later there is evidence of our own species, *Homo sapiens*, beginning to use the fossil remains of plants and animals. The circular forms of some fossils in particular, such as crinoid segments, were eminently suitable for fashioning into beads, while fossilized resin (amber) and coal (jet) were sometimes carved into ornaments.

In some cultures, myths and legends were inspired by observing fossil remains, while others found more practical uses. Ancient Egyptians used fossil tree trunks as logs for making corduroy roads over desert sands, and I have observed a fossilized crocodile tooth among funerary articles placed within a mummy's sarcophagus. At around the same time, the Etruscans beheld a fossilized cycad trunk with some reverence, but if these or any cultures questioned the origin of these attractive and sometimes useful forms, we have no record until the 6th century BC.

Among the Greeks were some who pondered the origins and nature of fossils. Xenophanes of Colophon noticed the presence of seashells on the hills of the island of Paros, as well as leaf imprints and other signs of fossil life in the rocks of Malta. He speculated that periodic floods were responsible for the transport and burial of marine life so high above the sea. Similarly, Herodotus, Pythagoras, and Xanthus concluded from observing fossil marine shells of far inland that the ocean must periodically cover what is dry land. But others developed more fantastic explanations for the origin of fossils, such as Theophrastus, who believed that rocks had a "plastic force" that created fossils. Such mystical interpretations would take root in the European sphere of knowledge, and for nearly ten centuries, there is little record of our relationship with ancient life through fossils.

In the renaissance, a young Leonardo DaVinci (1452–1519) participated in digging a canal in northern Italy. His observance of fossils there and later at

other sites would lead him to conclude that fossils were indeed of organic origin, and he outlined how plants and animals may be developed in rocks by the sedimentological processes we know today. But his notes were not published at the time, and without such dissent, human beings continued to think that fossils occurred through juices, forces, ethers, the biblical flood, and even the influence of the stars. The celebrated mineralogist and metallurgist of his day, Agricola (1494–1555) used the origin of the word fossil, *fodere*, to mean literally something that is dug up. His definition thus included not only the remains of once-living creatures but also ancient human artifacts, minerals, crystals, and rocks of all types. He believed that certain fossil forms such as ammonites, belemnites, and sharks teeth were of inorganic origin that precipitated within hard rocks in similar ways to ore forming solutions.

This view began to change when a Danish scientist Niels Stensen (1638–1686) compared fossil shark teeth in Tuscany to the teeth of living sharks and declared that fossils were once living organisms. This profound shift in sentiment laid a foundation for paleontology to be born as a science, but this would take several more centuries. Humankind gradually separated fossils in descriptions to become known as figured stones, and during the late 18th century, the term *fossil* dropped from use for minerals altogether

and their study evolved into a distinct branch of geology called *oryctology* *Petrefactenkunde* (or *Petromatognosis*, depending on which part of Europe you frequented). In 1825, French scientist H. M. Ducrotay de Blainville coined the term *paleontology*, which became popularized to reflect the growing zoological aspect of what was then a geological science.

In France in 1796, Georges Cuvier (1769–1832), generally recognized as the founder of the branch of paleontology devoted to the study of vertebrates, published that fossilized bones he observed were not from any animal alive and thus gave rise to the concept of extinction. J. B. Lamarck (1744–1829), known for his studies of invertebrates, connected fossils to living animals and established that many had gone extinct; he also characterized certain geological

layers by their fossil contents. Most important, Lamarck elaborated on how animals seem to change with time, providing support for the development of evolutionary theory, although his explanation for the mechanisms that cause evolution were flawed and not accepted at the time. During the course of many journeys across England as an engineer and surveyor, William Smith (1769–1839) realized that each layer of geological strata could be recognized and traced by the fossils found in it. This was the origin of *biostratigraphy*, using fossils to establish chronology and relatedness of strata, and Smith used it to construct and publish one of the first large-scale geological maps.

The stimulation of new ideas and applications of fossil data continues to grow. Today's paleontologist has embraced new technologies such as scanning electron microscopy that enables the viewing of submicron scale structures. Computers assist in seemingly endless applications, from three-dimensional scanning of fossils to reveal their hidden internal structures to the generation of super realistic life-models for study or entertainment to new mathematical and statistical models that assist in

describing and understanding patterns of diversification and phylogenies through time.

Taxonomy

The study of extant life is essential to the study of ancient life, and so biological sciences have always been considered in paleontology. Likewise, the paleontological information of extinct organisms assists in understanding the development and aspects of extant life. At the core of both biology and paleontology is a system to name and classify organisms to form a meaningful and practical hierarchy, the science of which we call *taxonomy*. The system was developed by Carl Linnaeus (1707–1778) and has been greatly modified and extended, but it still retains

the most fundamental unit, that of species. Species are groups of individuals that share a distinctive form and can interbreed with one another. Principles of taxonomy include using binomial principles of nomenclature to assign each species a unique name. Body fossils of animals are often disarticulated, but, due to most elements being readily identifiable, we can gain a more or less complete description and name assigned in the binomial form, genus, and species, as for extant animals.

Botanical fossils are also usually found as disarticulated parts, but there is greater difficulty in reconstructing the whole with confidence; we thus assign taxonomic names to the individual parts. In a related fashion, because we cannot link ichnofossils specifically to a particular species and representative behavior rather than actual body remains, we may adopt a unique classification scheme to enable comparison and study. A common method is based on the Linnaean system but is designed to reflect aspects of the behavior that formed the trace rather than morphology: resting (cubichnia), dwelling structures (domichnia), escape (fugichnia), moving (repichnia), grazing (pascichnia), farming systems (agrichnia), and feeding burrows (fodichnia).

Obviously, we cannot detect the habit of breeding in fossils, so we must rely on appearance and measurements of physiological elements—bone length, carapace width, and so on—to enable classification to species level. These measurements are also used to interpret the biology of fossil organisms and their structures in terms of their original functions, a discipline termed *functional morphology*.

This gathering of information within taxonomic frameworks allows the construction of *phylogenies*, models of connections between all groups of organisms as understood by ancestor/descendant relationships. These models can use the temporal dimension of fossil data to endow phylogenies with information about the tempo of evolution as well as the

Source: Photograph courtesy of Mark J. Thompson.

genealogical relationships among the lineages. Paleontologists express the relationships among groups of organisms through diagrams called cladograms. New tools such as molecular biology and the use of DNA are providing alternative ways of comparing and testing relationships of even extinct organisms. Although these newer approaches are of immense value, description will remain a vital component of paleontology to provide a source of enduring physical data.

Biostratigraphy

During the late 18th century, paleontologists realized that some rock formations could be characterized by their unique sets of fossil taxa and that the occurrence of some fossils was independent of the rock's lithology. Because organisms evolve and go extinct at different rates and most types have a geological life of only a few million years, a section of geological strata built up over time will have several fossil species occurring within it, confined to specific parts of the succession that represent the time when that species was living.

This enables our correlation of rock units over vast distances based on their fossil signature rather than their appearance, and we can establish time horizons in strata that could be of worldwide scope. This process is known as *biostratigraphy*, one of the products of paleontology that helps form the basis of many wider-ranging geoscience studies, such as understanding the

Source: Photograph courtesy of Mark J. Thompson.

duration and periodicity of geological events and providing a framework to explore sedimentary basins for petroleum.

Certain fossils are more suitable for use in biostratigraphy than others. The most excellent examples are called index fossils because of their ability to better resolve timescale boundaries. This process is helped if the fossil organism was abundant, common to different environments, fast evolving, geographically widespread, had high fossilization potential, and is readily diagnosable. Alternatively, there are *facies fossils*, those that show little change over long durations and are restricted to very specific environments, that may be of use in qualifying a succession. We can divide the stratigraphic range of fossil species into biozones that form divisions of the geological time scale, a process sometimes referred to as *biochronology*. In any sequence of fossiliferous rocks, the limited stratigraphic range of many fossil taxa is used for

correlation, typically by means of biozonation schemes where intervals are characterized by a species or group of species.

Biostratigraphy strives toward better taxonomic understanding because better understanding may result in our constructing biostratigraphic schemes with higher resolution. By integrating this paleontological data with other types of chronostratigraphic techniques, such as stable isotope studies, a more comprehensive and accurate understanding of geologic and life cycles emerge. This becomes even more important in studies of past climates and sea levels where good stratigraphic control permits more accurate prediction of future changes and their magnitude.

Commercially, we use biostratigraphy in the petroleum industry to assist in the location of oil and gas wells by increasing understanding of basin scale geology. In more modern times, the focus has shifted to smaller scale intrabasin geology, where biostratigraphy

can help develop an understanding of reservoir architecture and strategies to maximize production.

Paleobiology

We may view *paleobiology* as a synthesis of paleoecology and paleobiogeography, united in the study of how physical changes of ancient global geography and climate have affected the distribution and evolution of plants and animals, how ecosystems have responded to these changes, and how these responses have affected today's patterns of biodiversity. *Paleobotany*, the study of fossil plant life, can make interesting contributions to paleobiological studies. Because plants are sensitive to climatic changes, their distribution and abundance can illuminate much about ancient environments. Fossil vascular plants may also retain incredibly detailed data of ancient time, either directly by the growth rings in their trunks or indirectly. An example of the latter is in the Cretaceous age mangrove swamps in Egypt that show evidence of Cretaceous tides trapped in finely layered sediments among their roots. We can also use such data to show the difference in the length of a year, between ancient times to present, enabling calculation of the rate of slowing in the rotation of the earth.

The distribution of fossils is the domain of *paleobiogeography*. This provides information such as where organisms first evolve, their range, and the timing and extent of their dispersal. Such information can be critical in examining biodiversity of paleoenvironments, to determine factors of evolutionary processes and extinction events. Geologic and geophysical earth sciences have even used paleobiogeographic information in support of one of the most profound discoveries in earth science, plate tectonic theory. The paleontological evidence originated with the observation that some fossil assemblages on either side of the Atlantic Ocean were identical. This could be reasonably explained only by the concept of

an ancient single continent having split and drifted apart, separating in fact a single fossil record.

Extinction and Evolution

For naturalists and early earth scientists of the 18th century, the discovery of fossil bones of massive proportions caused a dilemma. Such bones were evidence of clearly monstrous reptiles that must still be roaming the earth, but where were they hiding? The concept of extinction did not exist until Cuvier argued that fossil remains clearly did not come from extant life forms but from those that must have perished in their entire lineage at some earlier time. This was quite a revolutionary thought at the time, but quickly became accepted on the basis of so much

Source: Photograph courtesy of Mark J. Thompson.

fossil evidence. This also caused issue with the prevailing biblical thought that all organisms created were immune to change and would never be allowed to become extinct. By using its vision of life over geological time, paleontology can provide the tools to more closely examine such extinctions and consider the factors and causes. This area becomes of growing concern as we have realized our rather limited understanding of ecological susceptibility to complex change and wish to prevent a similar fate for *Homo sapiens*, among other species.

Paleontology provides data that show that

- life is hierarchically based
- the fossil record is sequential
- organisms have changed over time

The conclusion of these facts is profound and a major contribution to our understanding of the physical world: that all organisms are related and share a common ancestor. Evolution study is a compound of various disciplines—pure biology, comparative anatomy, embryology, genetics, and population biology—and does not require paleontology and fossils to be supported. Paleontology is, however, indelibly linked to evolution because it is the science that holds life against the vastness of geological time, clearly illustrating the patterns that have occurred and the central tenet “descent with modification.” Paleontology answers questions regarding not only the

morphology of ancient life but also the pattern and timing of its development, thus becoming an invaluable instrument for testing the concepts of evolution.

Paleontological principles have long been important to physical anthropology; indeed, paleoanthropology is also called human paleontology. The disciplines share many approaches such as taxonomy, comparative anatomy, and phylogenetic analysis to address and explore the origins and development of early humans. Fossil evidence has been critical to displaying the evolution of hominids and elucidating the potential factors responsible for bipedalism, social groups, and even language. Although there is a perception that the fossil record of humans is woefully sketchy, there is, in fact, an excellent series of specimens compared to that of many

fossil animals. The morphological changes seen in this series contain powerful images of evolution at work. Even small fragments of fossil bone can provide invaluable data of the pathways upon which our direct ancestors moved. A single joint fragment can confirm stance; a single tooth can suggest diet.

We cannot escape the excitement of potential discovery as we look out over the Rift Valley and consider the antiquity of modern human beings lying just out of sight within the sediments of East Africa. But there is, perhaps, a deeper consequence of paleontological study. Fossils allow us to look further back than the prehistory of humans and to see the evolutionary pathways from microbial life to mammals to hominids. This may in some way remind us of our natural relationships with all species, as well of those of our direct lineage.

Infrastructure

The public perception of paleontology seems focused on the discovery of spectacular looking dinosaurs and expeditions to colorful deserts. While this is an extremely limited view, it is not altogether untrue. Of all the earth sciences that engage in field expeditions, paleontology is arguably elevated in human consciousness to one of quintessential excitement and discovery. Partly, this is in anticipation of what life form—unbeknownst before now—might emerge next from a rock layer, but more so because the

evidence we need to use for experiments may lack a natural supply. The ethos, then, of expedition and discovery is deep within paleontology as the only way to provide new evidence for study.

Although new paleontological discoveries may come about as much from the application of taxonomic analysis as to a geopick on an outcrop in a red desert, it is important to develop some insight into how paleontologists go about collecting and examining the objects from which they make meaningful conclusions and significant interpretations about ancient life.

The search for fossils is not haphazard and is usually a focused operation based on previously collected data with specific targets to find and hypotheses to test. Fossils can be located on every continent in a variety of terrains. Once found, as much detail as possible of the position and relationship with strata must be recorded. We must consider and note aspects of the fossil's taphonomy and we must take samples of adjacent sediments for micropaleontological and palynological analysis. We must construct a map and take careful measurements, for once a fossil is removed from its original position, all contextual data will be degraded. Depending on the type and size of fossil, it must be excavated and prepared for transport by wrapping it with plaster bandages or other strengthening techniques. Some large fossils necessitate considerable field engineering feats, such as plaster jackets, frames of tube steel, and cranes and bulldozers for transport. At some localities, paleontologists build display cases or even whole museums over a fossil deposit, such as at the dinosaur-rich Dashanpu Quarry in Zigong, China. The displaying of in situ fossils to the public can provide an exceptionally rich educational experience by representing similar conditions to that of field expeditions and their inherent element of discovery.

The removal and transportation of larger specimens from remote terrain and hostile environments can require major field operations. During the quarrying of dinosaur specimens at Tendaguru in Tanzania, 250 tons of fossil bones needed to be transported hundreds of kilometers through roadless jungle and

hills to the coast for shipping to Germany. The immense and heavy loads were suspended between poles on the shoulders of lines of porters. Today the challenge of exceptionally remote or difficult terrain may be met by helicopter to lift and remove a large fossil. The obvious downside of this technique is the danger that, under certain conditions, the suspended fossil may start swaying enough to destabilize the craft and cause the pilot to release the precious load. Happily, this is not the outcome of most expeditions.

Different types of paleontological data require different types of fossils to be collected. Most biostratigraphic specimens are now collected from drill holes that can penetrate deep into layers of strata under hundreds of meters of water or ice. The capability to sample such a contiguous sedimentary column would have been unthinkable a century ago, when sampling

was restricted to surface exposures of small sections of strata and the occasional surreptitious use of a mine.

Ichnofossils require similar field infrastructure. Footprint tracks may be retrieved for study and display but this is rarely achieved or indeed warranted. Most are recorded by mapping, drawing, photography and computer analysis, and taking latex casts of important or representative tracks.

Preparation

Once a fossil is retrieved from the field and safely deposited at a preparation facility, the remaining matrix can be removed under more controlled conditions than that of the field. A wider range of glues and solvents can strengthen and preserve the remains. The goal of the preparator is to ensure the long-term integrity of the specimen while destroying or removing the surrounding matrix. The challenge is that techniques for the matrix removal are usually deleterious to the specimen itself, requiring a balancing act.

Throughout centuries, human beings have used percussive techniques to better expose fossils for observation and study. In certain rock types, the inclusion of a fossil develops a plane of weakness easily exploited by the experienced collector with well-aimed hammer and chisel. Power tools automate and improve

the process, with modern electric or pneumatic pens and chisels now being specially engineered to minimize the vibration while still achieving the required penetration rates.

In certain specimens, the fossil is softer than the surrounding matrix and will be damaged by vibration from mechanical techniques of preparation, so chemical methods may be employed. The nodule or rock is suspended in a vat of dilute acids that are chosen to attack the matrix but not react with the fossil, leaving the fossilized portion to emerge, where it can be soaked with liquid preservatives and recovered, sometimes

in pristine condition. Chemical methods are also required for the study of some microfossils, such as pollen, that need to be liberated from matrix before being concentrated and mounted on new substrates for further study. Microfossil samples require slightly different preparation paths than macrofossils. Samples are collected from either drill cores or outcrops, and the microfossils they contain are extracted by a variety of physical and chemical laboratory techniques, including sieving, density separation by centrifuge, and chemical digestion of the unwanted fraction. The resulting concentrated sample of microfossils is then mounted on a slide for analysis, usually by light microscope. Taxa are then identified and counted.

Variants of sandblasting machines have become ubiquitously applied to macrofossil preparation. In these, a vibrating pressure vessel fluidizes an abrasive powder that is then propelled onto the specimen and abrades the matrix preferentially from the fossil. This work occurs in an air chamber where the abrasive can be retained and recycled.

Most macrofossils are delicate and require consolidating at the various stages of the removal and preparation process. The choice of consolidant is important as it may affect the fossil chemically for possibly hundreds of years. Some of those used in the past have shown degradation of strength and color over time and also

not proved amenable to removal in later preparation or maintenance. Modern consolidants include polystyrene beads dissolved in solvents such as acetone. The solution is absorbed into the pores of the fossil specimen before the solvent evaporates and leaves behind a supportive coating of plastic, suitably designed to be readily removable by other solvents. Cynoacrylate adhesives (superglues) have become increasingly popular for rapid repair of fractured fossils. Although their bond strength makes for slower reversibility and the long-term curative qualities are still being assessed, their utility and speed of effect has proven to be a boon to modern macro fossil preparation.

An overriding practice necessary to all preparation is the keeping of records. Written descriptions of materials and techniques used at the different stages of treatment assist future curators when a dismembered fossil needs to be reassembled. The advent of digital photography allows a pictorial record to be kept of progress and original form.

We must not underestimate the impact of the development of better techniques for preparing fossils. In some cases, previously described historic specimens have been reprepared to reveal new features of considerable importance. This has changed some phylogenetic relationships and may even lead to reclassification of the specimen to a different taxon. Old but significant specimens suffering increasing degradation with time can be preserved for further study and displayed to new generations of scientists and the public.

Modern Tools

The development of transmission and scanning electron microscopes in the late 1960s has been a significant aid to paleontological studies, providing microscopic images of high resolution, a variety of microscopic applications at a low cost, and a nondestructive practice. Applications in paleontological research include studies of skeletal microstructure and growth, functional morphology, and taphonomy. Quantitative and qualitative analyses of elements can also be undertaken, providing rapid detailed data of biochemical residuals and details of taphonomy such as diagenetic. During the earliest days of x-ray development, the technique was used on rock slabs to observe the fossils within. Modern paleontologists can now use MRI and CAT scanning to observe internal structures of fossil parts such as skulls. A

digital three-dimensional model of the skull can be manipulated to remove postburial distortion or it can be used to more accurately reconstruct the life-appearance of the fossil animal for technical studies or entertainment films. The same data can also be used to generate a three-dimensional plastic copy, thereby duplicating objects too delicate for typical casting and molding processes.

Tremendous advances in paleontology now stem from the use of computers. The compilation and analysis of large-scale databases of fossil species have allowed better views of the pattern and size of mass extinction events, the rate at which new species have appeared, and the standing diversity—a measure of the number of species on the planet at the time. By integrating paleontology with other sciences and technologies, paleontologists extend their view from the lithosphere to a more global system, with growing research on biogeochemistry, paleo-oceanography and paleoclimatology. The promise of these disciplines lies in their potential to shed new light on the workings of global systems, and, therefore, the state of our own biosphere.

As we begin to probe our neighboring planets, paleontologists may play a role in deducing the potential for life in extreme environments. With the evidence that liquid water once existed on Mars, it is plausible that the red planet may also contain fossils of life. If so, paleontology will provide the tools and methods to discover it among the red rocks of Mars.

PALUXY FOOTPRINTS

Found in the Cretaceous limestone of the Paluxy River basin in Texas, the Paluxy footprints are tracks—genuine, forged, and imaginary—that a number of creationists have notoriously adduced as evidence for the coexistence of humans and dinosaurs.

After a 1908 flood near Glen Rose, Texas, a number of large (15–18"; 38–46 cm) footprints, superficially and vaguely human in appearance and locally believed to be human in origin, were discovered in a limestone shelf (now dated to the lower Cretaceous period, about 113 million years ago) in the Paluxy River. During the Depression, both dinosaurian and “human” footprints were excavated, and sometimes forged, for the tourist trade. It was such forgeries that in 1938 attracted the attention of paleontologist Roland Bird to the Paluxy River, where he discovered genuine sauropod tracks, previously undocumented in scientific literature, as well as genuine theropod tracks. Articles in *National Geographic* and *Natural History* made the site famous.

Following his visit to the site, creationist Clifford Burdick proclaimed that the “human” footprints (which Bird was unable to identify) were indeed giant human footprints, and John Whitcomb Jr. and Henry M. Morris relied on his work in the founding document of modern young-earth creationism, *The Genesis Flood* (1960). Although there were a number of creationists who were skeptical, organizations such as the Institute for Creation Research and the Bible–Science Association, and a widely circulated film, *Footprints in Stone* (1972), popularized the interpretation of the footprints as human. In *Tracking Those Incredible Dinosaurs* (1980), the ICR’s John Morris attempted to provide a definitive creationist treatment along the same lines. In 1982, creationist Carl Baugh began to excavate new areas of the site, claiming to find clear human footprints as well as anomalous fossils and artifacts; although his discoveries were frequently rejected even by fellow creationists as absurd, in 1984 he founded a museum in Glen Rose to display them.

In 1982, a team of scientists—John Cole, Laurie Godfrey, Ronnie Hastings, and Steven Schafersman—calling themselves the “Raiders of the Lost Tracks” visited the site to investigate. They subsequently published the first scientific critique of the creationist interpretation; the Raiders failed, however, to examine the so-called Taylor trail, featured in *Footprints in*

Stone, which were thought to be the best tracks for the creationist interpretation. Investigations by Ronnie Hastings and Glen Kuban, who began studying the tracks independently in 1980, established that the Taylor tracks are of dinosaurian origin. The heel-like depressions on the posterior of the tracks, Kuban and Hastings concluded, were formed by bipedal dinosaurs leaving metatarsal impressions. When the traces of their tridactyl digits were obscured, due to infilling, collapse, or erosion, the result superficially and vaguely resembled a giant human footprint.

The results of these scientific investigations were acknowledged, albeit slowly and grudgingly, by the ICR and the producer of *Footprints in Stone*. But the Bible–Science Association continued to defend the creationist interpretation of the tracks as late as 1994, and Carl Baugh’s Creation Evidence Museum is still (in 2005) in business.

PALYNOLOGY

Palynology is the study and analysis of microscopic organic material, predominantly pollen and spores, but also a multitude of other organic particles with tough exterior surfaces that defy acid digestion, collectively known as Palynomorphs. Palynologists use the data on distribution and abundance of palynomorphs for a growing range of applications, from geology and archeology to paleoecology and forensic science, providing new insights and knowledge within each field. With the ability to resolve knowledge of ancient ecologies and climates, the application and

importance of palynology to humankind grows coincidentally with our concerns about global climate change and environmental impacts.

Palynomorphs are derived from four of the five taxonomic kingdoms (Protista, Planta, Fungi and Animalia) where organisms have some part of their life cycle that produces a cell, tissue or organ with a type of wall that is highly resistant to organic decay or inorganic degradation.

Throughout time, vast quantities of palynomorphs have been released into the atmosphere, each carrying the unique design of its species. Transported by wind or water, this organic dust occurs on almost every surface in nature and can be ingested by animals, intentionally or not, when they eat, drink, and breathe. But the majority of palynomorphs rain down from the air to accumulate in lakes, bogs and oceans where they are incorporated into sediments and will readily fossilize. As the world's vegetation changes, so, too, does the layered signature of pollen and spores in the geological record, preserving information of the plant assemblage at that point in time.

The predominant focus of palynology has been on spores and pollen grains. Ever since seed plants evolved in the Devonian period and spread across the planet, their reproductive structures evolved tough exteriors, the exine, to aid in dispersal strategies by resisting decay. The exine has walls consisting of chitin, a highly inert material related to cellulose, and sporopollenin, an enigmatic and nearly indestructible compound. This structural and chemical strength ensures that palynomorphs survive the rigors of transportation and sedimentation, making them ideal subjects for fossilization.

To study these microscopic objects, palynologists treat a sample of rock, soil, or other object with strong acids (such as hydrofluoric) to dissolve the constituents and leave an acid-insoluble residue. The tough exterior of palynomorphs protects them from digestion and thus concentrates them in the residue where they can be identified and counted.
